# THE LANCET

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology,
Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

226

VOL. CCX.

VOL. I. FOR 1926.

---

*ONE HUNDRED AND FOURTH YEAR.*

---

EDITED BY

SIR SQUIRE SPRIGGE, M.A., M.D. CANTAB., F.R.C.S. ENG.,

AND

EGBERT MORLAND, B.Sc., M.B. LOND., M.D. BERNE.

---

LONDON
PRINTED BY HAZELL, WATSON & VINEY LD., 52, LONG ACRE, W.C. 2, AND PUBLISHED BY THE PROPRIETORS
AT THE OFFICES OF "THE LANCET," No. 423, STRAND, AND No. 1, BEDFORD STREET, STRAND.
MCMXXVI.

# INDEX TO VOLUME I., 1926.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.*

**A Concordance of page numbers and dates of issue will be found at the end of the Index.**

---

## A

Abdomen, the acute, in childhood, 714
Abdominal and Pelvic Surgery for Practitioners (Rutherford Morison) (R.), 111
Abdominal disorders in childhood, some (F. J. Poynton), 604
Abdominal emergency, an unusual acute (O. W. Roberts), 1250
Abdominal muscles, the, 322
Aberdeen, S.M.O.'s report, 1002
Abnormals, The Great (Theo. B. Hyslop) (R.), 607
Abortion, contagious (A.), 1214
Abraham, Johnston, Marriage and gonorrhœa, 1095
Abscess and gangrene of lung (T. P. Williams), 130
Accident causation, the human factor in (A.), 613; prevention and school-children (A.), 721
Accidental hæmorrhage, ætiology of, 814; bacterial infection and (A.), 958; (C.), 1064
Acromegaly, glycosuria in (K. S. Hetzel), 440
Adami, J. G., Advance in medicine, with reference to the campaign against tuberculosis, 1027; treatment of malignant disease with lead, 543, 658
Adams, Joseph E., Cholecystogastrostomy for inaccessible gastric ulcer (C.), 1003
Adams-Stokes syndrome, pathogenesis of, 97
Adenitis, supraclavicular, unusual case of (F. Bodman), 340
Adie, W. J., Herpes zoster in spontaneous subarachnoid hæmorrhage, 124
Adrenalin for paraphimosis (C.), 530, 948
Adrian, F. A., Sympathetic innervation of striated muscle, 305
Aeronautics, early history of (A.), 298
Aeroplane, evacuation of sick by (A.), 28
Africa, East, medical service (A.), 189; A Naturalist in (G. D. Hale Carpenter) (R.), 767

AFRICA, SOUTH, CORRESPONDENCE FROM.—Bloemfontein Hospital Board, 44—B.M.A., visit of medical secretary of, 44—Campbell, Dr. S. G., death of, 780—Cape Town and venereal disease, 44—Defective Transvaal children, 780—Haworth, Dr. Wallace, death of, 780—Hospital deficiencies within the Union, 779—Leper institution, self-government in a, 44—Medical and Pharmacy Bill, re-introduction of, 780—Mother-craft, training in, 44—Natives, training of, as doctors to their own people, 779

Africa, South, bubonic plague in, 1278; miners' phthisis in: compensation claims, 928
African medical remedies and charms, 947
Air cleanser, "Doodoo," 1292
Air Force, tuberculosis in the (P.I.), 523
Air passages, foreign bodies in the, 112
Albuminuria in relation to life assurance, 62
Alcock, Lieut.-Colonel A., retirement of (A.), 725
Alcohol and drug addicts, legislative measures for the control of (F. S. D. Hogg), 163
Alcohol, excretion of, in urine, as guide to alcoholic intoxication, 207
Alcoholism and tuberculosis, 43
Alcoholism, recrudescence of, 106
Aldrich-Blake, Dame Louisa, death of, 27; (O.), 101; memorial to, 1197
Aliphatic compounds, non-volatile, in general anæsthesia (R. K. Lambert), 121
Allen, F. E., on cancer and the general practitioner, 602
Allen, Sir Harry Brookes, death of, 790; (O.), 835
Allison, T. M., Danger of opium in combination with other drugs (C.), 1280
Alston, Dr. Ronald Bruce, death of, 791
Amalgam fillings, dangers of, 1276
America, medical examination of passengers to (C.), 518
American Child Health Association: health survey of 86 cities (A.), 80
American Heart Journal, the (A.), 148
American tour in Europe, 929
Amino-acids, influence of, on bacterial growth, 442
Ampthill, Lord, presentation to, 100
Amputation: a legal decision, 1073
Anæmia, treatment of (Alexander Goodall) (M.T.T.), 1160, 1216
Anæmia, pernicious, case of, of aplastic type (L. E. H. Whitby and R. Jackson), 230; importance of bacterial hæmolysins in, 442; treatment of, 1160; secondary, treatment of, 1216
Anæsthesia, gas and oxygen, in general anæsthesia (J. R. McKenzie), 238; general, non-volatile aliphatic compounds in (R. K. Lambert), 121; hedonal, 122, (C.), 267; Local, of Face and Neck: Lehrbuch der Lokalanästhesie des Ohres, &c. (Cæsar Hirsch) (R.), 557; oxygen and, 918; respiration and (A.), 662
Anæsthetic apparatus, improved (H. F. G. Boyle) (N.I.), 1044
Anæsthetics, deaths under, the Coroners' Bill and (M.L.), 80
Anaphylaxis, digestive (A.), 1050; white wine, 214
Anatomical blackboard, an, 60
Anatomie Medico-Chirurgicale (Philippe Bellocq), Fasc. I. (R.), 1207
Anatomy for Artists (E. Wolff) (R.), 605
Anatomy: Grundriss der Wissenschaftlichen Anatomie (Wilhelm Lubosch) (R.), 717
Anatoxin, protective value of, 1058
Ancient Civilisations, The Healing Gods of (Walter Addison Jayne) (R.), 240
Anderson, Lieut.-Col. John Allan, appointed Inspector Cruelty to Animals Act, 944
Andrewes, Sir F. W., Linacre lecture on disease in the light of evolution, 1075
Andrews, Alban, on pyelography, 287
Andrews, Henry Russell, Common difficulties in labour met with in general practice, 970
Andrews, W. Horner, on Hodgkin's disease in animals, 287
Aneurysm of a sinus of Valsalva bursting externally (J. H. Sheldon), 178
Angiolymphe (Zimmermann) (R. & A.R.), 446
Ankle fractures, manipulative treatment of (W. A. Cochrane), 93, (R. Ollerenshaw), 96; operative treatment of (H. A. T. Fairbank), 97; (W. H. Trethowan), 99; remote results of treatment of (S. T. Irwin), 94
Ankle-joint, Introduction to discussion on fractures in the neighbourhood of the (Harry Platt), 33; discussion on, 90
Ankylostomiasis, toxicity of carbon tetrachloride in the treatment of (M. Khalil), 547
Anniversary, a scientific (A.), 772
Antenatal care, some practical aspects of, 1144
Anthrax, human, treatment of (Adrianus Pijper) (M.T.T.), 88, (C.), 203; in the wool industry of Bradford, history of, and of its control (F. W. Eurich), 57, 107
Anthropology: Les Races et les Peuples de la Terre (J. Deniker), 2nd edit. (R.), 1208
Anthropometric formulæ, Dreyer's, applicability of, to boys (D. C. Jones), 945
Antimony, tartarised, lead and arsenic in (A.), 188; (E. Griffiths-Jones), 194
Antimony tartrate injections, intravenous, biochemical action of (J. B. Christopherson and S. Roodhouse Gloyne), 227
Antiphlogistine (R. & A.R.), 21
Antirabic inoculation (A.), 406
Antitoxin production, specific factors and (A.), 505
Aorta, syphilis of the heart and, 400
Aortite Postérieure, Les Syndromes d' (Ch. Laubry and others) (R.), 347
Aphasia (S. A. Kinnier Wilson) (R.), 1207
Apothecary, the title of (C.), 1226, 1280
Appendicitis, peculiar pain in (C.), 268
Apples, arsenic in (A.), 30
Appointments, weekly lists of, 50, 100, 161, 211, 264, 319, 374, 425, 474, 528, 582, 634, 689, 740, 791, 840, 892, 941, 1017, 1070, 1125, 1180, 1237, 1290
Arabian Medicine and its Influence on the Middle Ages (Donald Campbell) (R.), 912
Archer, death of Dr. William, 683
Architect, the function of an, 630
"Ardente-acoustique" electrical aids for the deaf, 1293
Ardeshir, K., A case of gangrene of the nose due to diabetes mellitus, 1250
Arms, congenital defect of (A.), 674
Army, health of, in 1923 (A.), 243
Arsenic in apples (A.), 30, 604, 824; in fruit (P.I.), 680
Arsenic and lead in tartar emetic (A.), 188; (E. Griffiths-Jones), 194
Artères de la Peau chez l'Homme, Etude Anatomique des (Mme. P. Bellocq) (R.), 1207
Arthritic muscular atrophy (A.), 1106
Arthritis, chronic, non-specific protein injections in (W. Yeoman), 1216
Ashcroft, G. W., Renal rickets, 865
Aspirin with Dover's powder, tablets of (P. D. and Co.) (R. and A.R.), 660

Assaying of Brabantius, The, and Other Verse (C. S. Sherrington) (R.), 445
Association of Special Libraries and Information Bureaux, 629
Asthma, bronchial, operation for, 997; The Treatment of, by Intravenous Injections of Peptone (P. Boot) (R.), 606

∴ ∴ palatable emulsion of ∴ ∴

**B. ACIDOPHILUS** (about 250 millions per c.c.)

AGAR-AGAR, PETROLAT. liq. (heavy) SACCH., flavouring.

Indicated in Constipation, Intestinal Stasis with Chronic intestinal putrefaction, etc.

---

While the B. bulgaricus cannot establish itself as an inhabitant of the intestinal tract and soon dies off, the B. acidophilus, being a native of the bowel, very quickly establishes itself in its normal habitat and multiplies freely.

BACTOL will acidophilise the intestinal tract and thus correct putrefaction characterised by flatulence and foetid faeces.

# Convocation Address

ON THE

# WIDENING RANGE OF MEDICINE.

*Delivered at the Congress of the American College of Surgeons held at Philadelphia in October, 1925,*

BY LORD DAWSON OF PENN, G.C.V.O., M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL; PHYSICIAN TO H.M. THE KING.

---

MR. PRESIDENT.—A double honour is my portion—your fellowship and the delivery of this address—and let me say how deeply I treasure it. If my expression of gratitude is brief, it is out of regard for the many other claims on your attention. I will ask you, then, to liken my appreciation to the small hand of the clock which, though ranging one-twelfth of the distance of the long hand, signifies 12 times as much.

We have just witnessed a short but moving ceremony—the conferring of the Legion of Honour by Dr. de Martel upon Dr. Charles Mayo. The honour and the services of the recipient are alike unique in distinction. To all of our tongue in whatever land they be, this recognition, not only of a great mind but of *a genius for friendship, will bring rejoicing.*

In the choice of a subject suitable to this occasion I was influenced by the knowledge that laymen, both interested and distinguished, would constitute a *portion of the audience; so it occurred to me to present* for your consideration how, on the one hand, medicine is increasing its contact with the sciences, and on the other hand, is extending the range of its influence to cognate activities in the body politic. Medicine has, so to speak, an outer and an inner temple. In the inner temple thought reigns, and in the outer action becomes the handmaid of thought. *During the* twentieth century progress in its sciences has been so notable that medicine has received fresh direction and inspiration. Thought is vivid, new pathways are opening out, and the time is instinct with new unfoldings. And yet we should not forget the debt we owe to the times which have preceded us. It has often been that we have reaped because they have sown, and their achievements measure large when the slenderness of their resources is remembered

century, befogged by fanciful reasoning and fantastic treatment. It could not shake itself free from habits of thought which had their origin far back in primitive beliefs in magic and hostile deities. And in present times so persistent is tradition, the world is still imbued with belief if not in magic yet in the magical, to the detriment of its true interests. To quote Garrod in his eloquent Harveian oration:

> ". . . . The primitive medicine and the art of the medicine man survive to this day among the savage races of the earth, and he would be a bold man who should deny their survival amongst those races which regard themselves as the highest products of civilisation. Are any of us wholly free from such ideas?"

It is difficult for us to convince the public that we have no wonders to offer except those to be found along the narrow and straight path of rational endeavour, and this is especially true in the realm of therapeutics. We in the profession might set example by a more critical examination of our ways and means. We are apt to forget how many of our remedies and formulæ have descended by apostolic succession from previous generations. In order to illustrate, not what our formulæ are but from what they have descended, let me quote you "An Excellent Medicine for the Dropsie made for Queen Elizabeth by Doctor Adrian and Doctor Lacy":

> "Take Polipodium, Spikanard, Squat, Ginger, Markoram, Galingal, Setwel, of each a penny weight, Seina leaves and cods, so much as all the reſt groſly beaten, put them into a bag, and hang it on an earthen pot of two gallons of Ale, and every four dayes cover the pot with new Barm, and drink no other drink for ſix daies, and this ſhall purge all ill humors out of the body, neither will it let the blood putrifie, nor flegme to have domination, nor Choller to burn, nor Melancholly to have exaltation, it doth encreaſe Blood, and helpeth all evill, it helpeth and purgeth Rheum, it defendeth the Stomack, it preſerveth the body and engendereth good colour, comforts the ſight and nouriſheth the Mind."

There are features of this prescription which might make it popular to-day and even in this country! *And yet in that grey light there were glimmers in the* sky. For instance, digitalis was in the Pharmacopœia of 1605. Another example of cycles in knowledge is to be found in the fact that Gairdner recommended iodine for goitre 100 years ago. And that is dwarfed when we learn from Prof. Schmidt that a herb, Ma Huang, containing an active principle similar to adrenalin, was sanctioned by the emperor, Shen Nung, and used over 5000 years ago.

the perversities, of his symptoms, and to either prepare him for operation or even excuse him operation, or guide him to convalescence. Such coöperation with medicine will bring you results hitherto undreamed of. Is it not possible that bio-chemistry helps to measure the physical aspect of individuality? In the days when acute infections played so dramatic a part in life and death amongst peoples, when medical men were so largely occupied with their visitation and impressed with their own relative powerlessness to battle against them, it was only natural that thought should envisage disease more as an evil force from without and set less value on the qualities belonging to the patient.

The banishment of typhoid and other fevers from our midst, the power over the protozoal diseases, the diminishing force of tubercle and syphilis, even acute rheumatism with the damage it inflicts on young life, is less powerful for evil—these and other achievements bear witness to a changing scene.

### THE STUDY OF THE INDIVIDUAL.

The subinfections which play a relatively larger part in the health problems of to-day bring home to us the importance of the individual or host, and the make-up of his body and mind. Their activities in each individual would seem to be determined by some internal factor—some nidus or influence which is probably specific for that person. Thus an attack of rheumatoid arthritis from infected teeth is determined as much by the internal factors individual to that patient as by the infective agent; and not the least suggestive feature of the recent advance in our knowledge of malignant disease from the brilliant researches of Gye and Barnard is the importance of this internal factor in the production of the disease. In short, specificity of the soil looms as large as specificity of the infective agent.

From another point of view this concern of medicine for the individual man—his resistance—his qualities which make for good and for evil, pushes disease back to its beginnings. We thus become concerned with the fascinating though difficult study of trends and tendencies, with the border country between the physiological and pathological, and this leads one to reflect that the limits of the physiological widen with the advance of civilisation. And the body, like the mind, has its inborn traits. Physiological habit corresponds to character. Who is to say where peculiarity ends and fault begins? Advancing age tends to harden peculiarity into fault. Moreover, what we view as peculiarity in ourselves we are apt to term fault in other people. Thus determination becomes obstinacy, and strong will becomes self will, and conviction becomes obsession; and the latter suggests that the philosopher will make his convictions merry, so that his old age may possess content. On the physical side let me instance essential hypertension; no doubt this is sometimes an acquired condition, but equally often it is an inborn, a physiological habit, an over-responsiveness of the vasoconstrictor mechanism which begins as a peculiarity and may end as a fault or disease, commences in the realm of the physiological and ends in that of the pathological. The irritable heart, the over-responsive abdomen are other examples. Our object should be to take cognisance of habits and trends, and so guide their human possessor that his potentialities operate for his good, not for his harm.

### THE RÔLE OF THE FAMILY DOCTOR.

Here, then, there is contact between medicine and education—their spheres overlap, their needful aptitudes resemble. The qualities of mind needed in a diagnostician are as essential to the teacher as the doctor. And from this I am led to reflect that teach- will become a prescribed duty in the doctor's . How can it be otherwise? If we are to get beginnings—if we are to guide people in the f health, if the community guards the health hers, its babies, its school children, its industrial workers, the family doctor must become an educationist and in part a health administrator.[1] If he does not, his rôle will suffer progressive diminution, curtailed as it will be on the one hand by the whole-time health official, and on the other hand by the invading specialist. This will, in my judgment, be a disadvantage to the community. The family has need of its own doctor, known and trusted, and it is with his guidance its members should get all that is best from specialism, and this is the more necessary in a day when specialisation begins early in the doctor's career and is apt to become restricted in vision. The family doctor should remain the foundation of medical service, but his outlook, functions, and training need modification to meet changing needs. First must come his care of the sick, but beyond that he will have communal and educational duties.

Take, for example, the value of medicine towards industry, the physical fitness of the worker, the survey of his environment, the gauging of the suitability of body and temperament to the work required, the strains connected with specialisation, and that new large field of research into the problems of industrial fatigue. In all these things, which concern not only the health and happiness but the efficiency of the worker, medicine has responsibility. Few doctors in a community could fulfil the whole range of such demands. I suggest that in the future the doctors of a district will form themselves into a "faculty" which would place the varieties of knowledge and experience of its members at the service of the community, and in its collective capacity exercise a powerful and much-needed influence on public life.

Withal let us do nothing which would impair the personal touch—the deep and abiding interest which mean so much in the hour of sickness, for our rosary needs to be strung with the beads of love as well as with those of thought.

### THE HOSPITAL: PRESENT AND FUTURE.

How, then, are the members of this local faculty to hold high their standard of work? The answer is, by the hospital. Every district, however rural, should have a hospital adapted to its needs. For myself, I should like to see the conception of such a hospital widened to that of a health centre where curative work, clinic, wards, communal services, educational facilities could find a home, where doctors could improve their minds, give of their best, and find encouragement and restraint. And in this connexion is to be found one of the most beneficent activities of this illustrious College. This larger view of the district hospital carries with it a wider conception of the art of healing. Dietetics, physiotherapy belong as much to education as to healing.

With greater knowledge we have come back to simplicity. The surgeons first found salvation in fire by the discovery of asepsis, and the rest find in air and light a romance of healing. Who would have thought a few years ago that the simplest of hospitals, built on the cattle-byre type, with open air, sun, good food, aided by a knowledge of anatomy and physics as their only armamentarium, would have produced the transformations to be found in modern orthopædic hospitals?

And the beneficial results extend far beyond the patients cured, for each one of the latter becomes a missionary of health—a nuisance to his family, in that he enforces upon its members light and air, to their surprise, discomfort, and salvation. For one cured, many are saved; which dictum is further emphasised in the hygiene of the mouth, for the treatment of oral sepsis has done even more by its terrors than its cures.

---

[1] The considerations here set forth are apposite to the misgivings which have found expression in Parliament and the press on the attitude of our General Medical Council towards professional conduct and unqualified practice. Though these misgivings are for the most part based on misapprehension as to what medicine should stand for, they none the less need to be fathomed and adjusted in a large-minded spirit.

### Hormones.

Next, may I let chemistry lead me to another line of thought. The discovery of hormones by Starling gave to chemical products a direct control of function. Consideration of the rôle of these chemical messengers, of which $CO_2$ may be said to be the exemplar, gives us a wider comprehension of the wisdom of the body, and the physical scope of, say, secretin and insulin is within our ken and gives clearness to our conceptions and range to our activities. But that minute quantities of a chemical product, the output of a group of cells, should so far be the arbiter of the physical and mental states of the body that its presence will decide whether the body is to have, or not, vigour and beauty, and the mind power to think and remember, leaves one almost dazed with wonderment. And yet—so it is, as the isolation of the active principle from the thyroid gland exemplifies. Again, it would seem that secondary, and to less extent primary sex characters are the result of chemical substance originating in specialised groups of cells, and such bodies not only determine sex at the outset, but will change sex characters during life's progress; and with the bodily changes will be the corresponding modifications of mind and character, and if one goes one step further and contemplates the beautiful attributes of the mother instinct, which have inspired the art and religion of the world, as resulting from stimulation by a chemical product, are not the limits of our comprehension passed, and our minds unsatisfied? Is the hormone the influence itself or the embodiment of the influence? Or is it the physical counterpart of the spiritual quality of influence? There are, in both, the same qualities of subtle and reiterated effect; in both of them we get a detachment from the material conception of mere bulk and weight and our minds glide back to the "little leaven" and "the grain of mustard seed." The rôle of the infinitely small carries thought to the border country of the material.

### The Place of Psychology in Medicine.

From this it is but an easy step to my next theme—viz., the place of psychology in medicine, which term I take to signify the study of the mind in health and illness. This must claim more of our attention, partly because the knowledge of mind has made striking advance and partly because the need for its help increases. And psychology needs to be taken into the texture of medical practice and not regarded as an extraneous aid. Its delicate processes, requiring as they do insight and sympathy, find encouragement and balance if they are as the warp to the woof of physical symptoms. Standing apart, psychological practice may easily fail in acceptance and purpose and even produce antagonism. This is due in part to the outlook of patients and in part to the crudity of many of its exponents. Broadly speaking, patients regard disturbances of mind as things they can, and disturbances of body as things they cannot, avoid.

Although neurosis is equally if not more prone to attack the higher type of mind, its diagnosis is apt, in spite of every explanation, to debase the patient and prejudice cure. So it happens that the physical and psychical should, wherever possible, be handled together. Priority of presentation should be given the physical, and it should be remembered that the disturbed mind is often helped best by treatment which is incidental and even unwitting. This is only another way of saying that the finer thoughts and feelings may be killed by attempts to give them a too concrete form. And yet, by a strange irony, there is a school of psychological medicine, earnest in advocacy, which has presented us a picture of the human mind and its processes, so crude and unattractive as to prejudice the acceptance of the great and valuable learning on which it is based.

For in truth, medicine owes a great debt to those teachers, Freud and others, who have disclosed to us the workings of the unconscious mind and their relations to those of the conscious. The principles of these teachers are not less true because the latter overstressed the rôle of the sexual instinct, and their disciples have mistaken the wood for the trees. And the conditions of modern life, its speed, its complexities, the fact that mechanical invention has outstripped man's power of adaptation, must not only produce exhaustions but set up strains, conflicts, and make the mind enter more into the make-up of illness than in the placid days of yore. And so it happens that not only do neuroses become more common, but physical illness is apt to be overlaid and inter-threaded with troubled states of mind. Clinical values have changed. And the vagaries in the manifestation of disease which so often vex its unravelling are sometimes the result of mind reactions—of personality.

How often do we not find that an illness with a physical basis which is perhaps amenable best to surgical interference, may have a superstructure of functional disturbances due to present or buried mental experiences, not only perplexing the patient and doctor but prejudicing recovery. Thus is explained why some operations cure the condition but not the patient. It is an interesting reflection that, while on the one hand the technique of diagnosis is growing in range and reliability, on the other hand the problem before it grows in complexity. This tells us that laboratory technique, though essential, is not all-sufficient; it throws light on the morbid process but not on the reaction of the latter with the patient. It leaves individuality untouched, unless, as is possible, variations in biochemical reactions may in the future disclose a correspondence with variations in bodily and mental functions.

### Psycho-Therapy.

I will next refer to the handling of the mind factor in disease. For reasons I have given, the technique of psycho-analysis, suggestion, and hypnotism, though in specially skilled hands and in exceptional cases useful, are in general medicine seldom necessary or desirable. The mind cannot, like the body, always stand set and formal treatment, for the texture and interlacing of the threads of its web are too delicate. Exploratory operations on the mind do not always heal by first intention. The best treatment often lies in comprehensive diagnosis, and by that I mean the unravelling and exposition, not only of the nature of the morbid process, but the physical and mental states associated with it.

Sort out a patient's symptoms for him. It is not things, but the significance of things which matters. Discomforts ignored in health are liable in neurosis to become obtrusive and produce fears. Such may impede the cure of bodily illness; or a function may be raised in consciousness; or again, a conscious experience may be misinterpreted and assume a sinister significance; or again, exhaustion may lessen control so that an instinctive tendency naturally suppressed rises up and produces conflict. Such factors must, in my judgment, contribute increasingly to the make-up of illness and demand our recognition. Explain causes, dissolve doubt, and, side by side with the best physical treatment, restore perspective, and the path to recovery and contentment opens out. An important part of therapeutics is a willingness to listen, a perceptive, understanding mind, and lucid persuasive exposition.

To those who have now been received into your Fellowship may I offer my felicitations and good will. A great heritage and an inspiring outlook are theirs—quest of knowledge, the beauty of craft, the privilege of help and healing, the leadership of their communities towards increasing health and contentment. As between nations medicine stands for reason, bearance, and mercy, and with the English-s peoples it is a beacon light showing the way understanding and the unity of an ever friendship.

## ON SOME
# NEW METHODS, DEVICES, AND APPARATUS
## FOR THE ROUTINE AND THE RESEARCH LABORATORY.

By Sir ALMROTH E. WRIGHT, M.D., F.R.S.,
PRINCIPAL OF THE INSTITUTE OF PATHOLOGY AND RESEARCH,
ST. MARY'S HOSPITAL, LONDON, W.

Of recent years a signal change has come over the spirit of medicine. It is not very long ago since the thoughtful physician believed that the methods of clinical observation and physical exploration would conduct him to his goal, and believed further that it was no part of his office to explore in his patients the biological events which lie outside the ken of our unaided senses. In contrast with his predecessor, the physician of to-day realises that direct observation and physical exploration cannot lead him far, and that he must, for the understanding of his cases, rely very largely upon *laboratory methods*—meaning here by *laboratory methods* all procedures, whether applied in the laboratory or ward, which render manifest things that are imperceptible to our unaided senses.

Medical research has passed through a precisely similar evolution. The earlier research worker was content to restrict his observations to the data furnished by the unaided senses. Pasteur, for example, in his immunisation work, took cognisance only of phenomena such as the survival, sickening, and dying of inoculated animals. In other words, he was content to employ the method of the *saltus empiricus*—the method by which we overleap all intermediate and "*subperceptible*" events to a final result which becomes visible to the eye. Since that the research worker has been learning his lessons. He has learned that only very few problems can be resolved by the method of direct observation. He has learned, further, that problems which have been resolved by this method (let us think here, for instance, of small-pox vaccination) have been only quite superficially resolved. And he has learned, lastly, that the intimate mechanism of things cannot be laid bare except by resort to appropriate laboratory methods.

Herein lies the justification for the publication of new laboratory methods, devices, and apparatus. Inasmuch as it is this latter which must first be taken into account, the description of the procedures in the following will in each case be prefaced by explaining how the necessary apparatus is made.

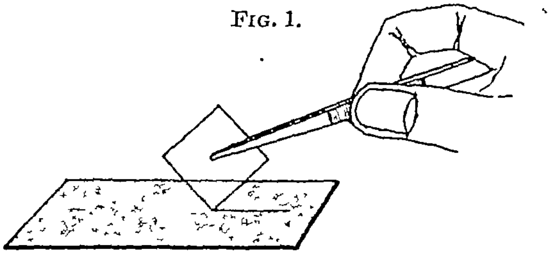
### Cover-glass Cells.

For the proper display and enumeration of such elements as red and white corpuscles, or microbes, or bacterial colonies growing in fluid, we require in each case to have at disposal shallow cells of standard depth. The hæmocytometer, of course, provides such a cell, and so does the slide-cell described in a previous paper.[1] The hæmocytometer has the grave defect of being expensive. Further, in the hæmocytometer cell the depth of fluid cannot be altered to suit different requirements. And, again, the hæmocytometer cell does not lend itself to sterilisation and to conversion into a culture chamber such as is required in connexion with measurements of bactericidal power. The slide-cell, though it provides ideally convenient culture chambers, falls short in the respect that its lid, made as it is of a microscopic slide, does not allow of the examination of the contents of the chambers with high magnifying powers. With a view to remedying these defects of the hæmocytometer and the slide-cell the cover-glass cell was devised. It is designed upon the [illegible] simple principle that a known volume of fluid [illegible] under a cover-glass of known area will, [illegible] of fluid from under the cover-glass is prevented, give a layer of fluid of known and (assuming that the cover-glass and slide are nearly flat) of approximately uniform depth.

### *The Simple Cover-glass Cell.*

Here the escape of fluid from under the cover-glass is prevented by coating the edges of the cover-glass with vaseline. The device for applying the vaseline to the edges of the cover-glass is to place a very small pellet of vaseline upon a slide and then melt this down by heating the glass. While the vaseline is still liquid we grasp a cover-glass in a pair of fine forceps and trundle it upon its edge over the surface of the vaselined slide in the manner indicated in Fig. 1. When a cover-glass thus edged with vaseline is imposed on a drop of fluid we have made what we may call a *simple cover-glass cell.*

Fig. 1.



Showing how the edges of a cover-glass are coated with vaseline by trundling it over the surface of a hot vaseline-covered slide.

### *Hinged and Walled Cover-glass Cell.*

A second form of cell—better in the respect that it can be used both as a counting and a culture chamber—is the following.

*Method of Construction.*—A microscopic slide is carefully cleaned and is passed through the flame to sterilise it. A cover-glass is similarly prepared. The latter is laid down upon the slide. With a soft paint-brush melted vaseline is now painted round its edges, the vaseline being allowed to overlap the edges to the extent of a millimetre or two. One of the corners nearest the worker is left unvaselined to facilitate lifting the cover-glass (Fig. 2, A). We further require to make a hinge upon which the cover-glass can be flapped up and down without lateral dislocation. That hinge is provided by thickening the vaseline rim and allowing it to overlap a little more along the edge which is farthest from us.

When the time comes for filling the cell a thin knife blade is inserted under the bare corner of the cover-glass lid, and this is lifted up until it stands upright upon the hinge that has been constructed (Fig. 2, B). The prearranged volume of fluid is then filled in from a pipette which has either been paraffined at the tip or has been drawn out into a fine point. If the fluid in question is blood, or any suspension in which the solid particles bulk as largely as they do in blood, not less than 30 c.mm. should be filled into the ⅞-inch cover-glass cell, so as to provide a sufficient depth of fluid, and the fluid should be deposited, not as a solid drop in the middle of the floor, but in the form of a ridge running out at right angles from the middle of the hinge. If these precautions are observed and the cover-glass lid is let down very slowly upon the fluid, an uneven distribution of the corpuscles or other suspended material will be avoided. When the cover-glass has been let down upon its bed the cell is sealed up by painting additional vaseline round its edges (Fig. 2, C) We may call the sort of cells we have been here speaking of *hinged and walled cover-glass cells.*

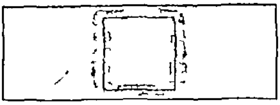
*The simple cover-glass cells* may be employed as *counting chambers* for the enumeration of red and white corpuscles or bacteria.

*The hinged and walled cells* are used: (*a*) As *bacterial culture chambers.* Such chambers find useful application: (*a*) when we want to count the living, as distinguished from the total bacterial content of a culture, or to count the living microbes in a quantum of culture used for a bactericidal experiment; (b) where we want to discover whether a particular microbe can cultivate itself in blood or any other medium; or to determine whether an addition, and if so, what addition, of a vaccine or other chemical agent will impede or abolish such growth.

---

[1] The Lancet, 1923, i., 365.

FIG. 2, A.

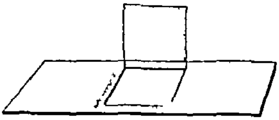


Vaseline hinged and walled cover-glass cell. The cell before opening.

(b) As *emigration chambers*—for the procuring of cover-glasses carpeted with, or of cells covered roof and floor with, leucocytes obtained direct from the blood

The methods of employing the cover-glass cell for these several purposes may now be very briefly described.

FIG. 2, B.

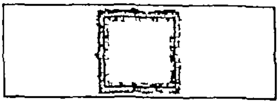


The cell opened for filling, showing the cover-glass standing upright upon the vaseline hinge

*Enumeration of the Red and White Corpuscles.*

(1) Blood suitably diluted with 8 per cent. magnesium sulphate coloured with methyl violet is introduced into the cell in the manner previously described. The appropriate magnesium solution is a saturated solution five-fold diluted to which about one-tenth of a 1 per cent. solution of methyl violet in water has been added. For counting leucocytes a dilution of 1 in 50 of blood and for red corpuscles one of 1 in 500 will give convenient counts. These dilutions are made on a paraffined slide with a paraffin-tipped pipette in the manner described in the author's "Technique of the Teat and Capillary Tube."[1] A suitable cover-glass to use is one 20 mm. (¾ inch) square—i.e., one with a superficial area of 400 sq. mm. Forty c.mm.

FIG. 2, C.



The cell reclosed after filling

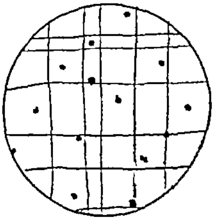
area), 0·1 mm. *Volume of diluted blood in the field of the microscope*, 0·05 c.mm. *Volume of undiluted blood in the field of the microscope* (assuming the blood to have been diluted 50-fold), 0·001 c.mm. And now, assuming that the average number of leucocytes per field had worked out as 7, the figure for the number of leucocytes in 1 c.mm. of blood would work out as 7000.

The method of calculation is similar for a red corpuscle count, except that here allowance must be made for the ten-fold greater dilution of the blood. When the cell is used for the enumeration of the microbes the procedure is similar to that used for counting corpuscles.

PROCEDURE FOR THE ENUMERATION OF MICROBES.

(2) Progressive dilutions of the culture are made (salt solution, broth or diluted serum being used as the diluent) and then the most suitable dilution (it will be one which furnishes only a very few microbes in the field of the oil-immersion field) is chosen for enumeration. Certain special difficulties, however, present themselves when we try to focus down upon small unstained objects when present in only very small numbers in a water-clear medium. Let us carry in mind here that we have in the oil immersion lens the equivalent of an extremely myopic eye which possesses only a very shallow depth of focus. Further, let us reflect that when we are focusing down upon a preparation such as we have here in view *there is nothing to give* us warning (unless by special providence a microbe happens to be in the exact axis of vision, and that does not [illegible] an adequate warning); there is nothing, I [illegible] to notify us of our having arrived at the upper limiting plane of our fluid, and again nothing to give us warning of our having arrived at the bottom of our layer of fluid. In default of such guidance we are liable to focus either too high or too low, and focusing too high means failing to see [illegible] objects, and *focusing too low* [illegible] our

FIG. 3.



Microbic colonies in the field of the microscope, enclosed between two systems of striæ—the vertical striæ between the lower face of the cover-glass and the horizontal on the upper surface of the slide.

edges of the papers upon the slide in such a manner as to impregnate these edges with paraffin. The border of paraffin which is in this way obtained serves to keep the blood when this is imposed upon the filter discs or squares from running off upon a subjacent surface. Our paraffin-framed discs or squares are now transferred to a sterile sheet of filter paper which is destined to supply the aspirating force required for our filtering operations. Everything being now prepared, we impose defibrinated blood upon our filters heaping it up upon them, and we now take care to bring the upper and lower filter papers into closer application so as to start the filtration In filtering care must, of course, be taken to prevent any portion of the filter running dry.

That a filter paper which has served for the filtration of blood contains in its superficial layers practically all the leucocytes of the blood, and in its deeper layers practically no leucocytes can be very easily demonstrated. We can satisfy ourselves of this by taking such a filter paper, treating it with water until all the hæmoglobin has been dissolved out, staining with logwood, mounting in balsam, and examining under an oil-immersion lens.

For the purpose of a comparative bactericidal test we prepare two such discs (Discs Nos. 1 and 2), also soak another precisely similar disc in serum (Disc No. 3), and then take a Petri dish containing nutrient agar, the surface of which has been evenly implanted with staphylococci. Then we place Disc No. 1 upper face downwards upon the agar; Disc No. 2 lower face downwards; and Disc No. 3 any way that it happens to come, and then cultivate at 37° C. for 24 hours. By that time all the microbes which have escaped destruction will have grown out into colonies, and will have invaded the substance of the filter paper discs, and inspection of these, beginning with the last and ending with the first mentioned, will show (1) that the serum has exerted no bactericidal power, (2) that the hypo-leucocyted blood has exerted very little bactericidal effect, and (3) that the hyper-leucocyted blood has exerted a very great deal Permanent show specimens can now be prepared by first soaking the filter papers in water, then staining by Gram's method, and then mounting in Canada balsam (Fig. 4).

### THE VAGINAL PIPETTE.

The vaginal pipette serves for evacuating the contents of lengths of capillary tube which are unprovided with mouthpieces—for example, stems of capillary pipettes which have been cut off from their butt ends.

The principle upon which the pipette is constructed will be understood from the description of the method of making such a pipette. We take a capillary pipette with tapering stem, and cut this down to a length of about 3 inches, and then again cut it across just below the neck of the pipette. We then coat the middle of the truncated stem somewhat heavily with sealing-wax, and heating the neck of the butt end in the flame we bring it down over what was previously the distal extremity of the capillary tube until it meets the sealing-wax. This lutes the two tubes together, giving us an inner tube with a trumpet-like aperture and a tapering upper end, and an outer tube upon which we can fit a rubber teat. When we now introduce into the pipette's trumpet-shaped mouth the tapering end of any open capillary stem, and push it home until grasped by the contracting walls of the tube, we obtain a practically air-tight joint (Fig. 5). When such an air tight joint has been obtained pressure on the teat will expel the contents.

This description of the vaginal pipette may conveniently introduce an account of procedures in which it finds useful application. The first of these is a *Simplification of the Procedure for M*

Capillary Tube" in the respect that after the phagocytic mixtures have been made and filled into the capillary pipettes and the tips of these have been sealed, the stems are cut off from the butt ends and are then immediately or after a very short incubation in the water-bath centrifuged. After a centrifugalisation, which may last on the average some 45 seconds, the tips of the pipettes are cut off, the contents are expelled and mixed by the aid of the vaginal pipette, and films are made in the customary manner. In a future communication the details and the advantages of this procedure will be fully described.

### *Simplification of the Method of Measuring the Coagulation Time of the Blood.*

The method here to be described is a simplification of the methods described in the first and second

FIG. 5.

FIG 5.—Vaginal pipette.

FIG. 6.

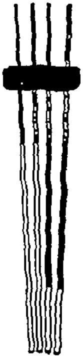


FIG 6.—Coagulation tubes fixed on a roll of plasticine. The left-hand two are depicted empty except for the paraffin lining in their upper tapering ends. The right hand two are shown with the columns of blood in position.

# IRRADIATION OF FOODSTUFFS WITH ULTRA-VIOLET LIGHT.

## A CLINICAL INVESTIGATION OF THE CURATIVE VALUE OF IRRADIATED FOOD IN RICKETS.*

BY HELEN M. M. MACKAY, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN; AND ASSISTANT PHYSICIAN TO THE INFANTS HOSPITAL, WESTMINSTER;
AND
HAROLD F. SHAW, M.B., CH.B. MANCH.,
SENIOR RESIDENT MEDICAL OFFICER, EAST LONDON HOSPITAL FOR CHILDREN; LATE HOUSE PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN.

ONE of the most interesting recent developments in medicine is the scientific study of the effects of light on the organism, its mode of action, and its therapeutic value in disease. The striking increase in well-being so frequently obtained from light treatment in this country appears to justify the conclusion that large numbers of city dwellers suffer from too little exposure to light, and that for this reason artificial light therapy has a wide sphere of usefulness. Its romance has caught the imagination of the public, a fact with attendant advantages and disadvantages, since on the one hand all have now heard of its value, and on the other there is the likelihood of exaggerated hopes leading to a reaction.

In artificial light therapy we are as yet only feeling our way, working empirically, with no clear idea of the relative value of different rays under different conditions, of the best dosage, or of how to grade it. The subject, too, is complicated by such phenomena as the interference of one group of rays with the effects of another.[1] Bit by bit, however, scientific knowledge is accumulating which will allow of a better understanding of the physiological effects of light. Two diseases—rickets and infantile tetany—are known to be directly associated with insufficient exposure to light, and consequently these lend themselves to investigation in connexion with light treatment—the former much more readily than the latter as its progress can be studied and demonstrated with the aid of the X ray plate; but knowledge developed in connexion with rickets will probably help our understanding of the mode of action of light in other conditions.

### *Therapeutic Effects Common to Cod-liver Oil and Ultra-violet Light.*

For some time interest has been aroused by the curiously parallel action of light and cod-liver oil (containing the so-called antirachitic factor) in relation to calcium and phosphorus metabolism. Either will cure the bone lesions of rickets [2] and will prevent the development of rickets on a rachitic diet,[3] either will increase the availability (probably by increasing absorption from the intestine [4]) of calcium and phosphorus in the diet, making a very small quantity adequate for the needs of the organism, and either will bring about the gradual rise to normal of a low blood phosphorus or blood calcium.[5] Both cod-liver oil and light therapy will induce growth in a rat given a diet deficient in the fat-soluble vitamins (A factor and antirachitic factor), but the duration of growth differs. If cod-liver oil containing these factors is added to the diet growth *continues* normally, but the growth caused by exposure to light is only temporary. After an interval—i.e., probably when the supply of vitamin A (in contradistinction to the antirachitic factor) in the rat's body is exhausted—the animal rapidly develops xerophthalmia and loses weight.[6] On the other hand, a rat on a "rachitic diet" can be protected ap[illegible]ly indefinitely against rickets by exposure to adequate light, a fact which appears to indicate that the action of light and of cod-liver oil are only interchangeable as regards the antirachitic factor and not the A factor.

### *The Activation of Lipoids by Light: Animal Experiments.*

Steenbock and Black [7] and Hess [8] were the first to correlate these facts, though many investigators are now working in this field. Steenbock and Black found that the presence of irradiated rats favourably influenced the growth of non-irradiated animals living in the same cage when all were on the same diet—namely, one deficient in the antirachitic factor. They suspected emanations of some sort from the radiated rats, especially since they found that an irradiated cage bottom exerted a similar beneficial effect. They worked with insulators, conductors, various metals enclosed in quartz flasks or exposed direct to the rats in their efforts to discover the nature of this emanation,[9] and finally the true explanation dawned on them and was confirmed by experiment. Exposure to ultra-violet light endowed certain foodstuffs with antirachitic properties. By irradiation of the cage bottom traces of fæcal contamination were rendered antirachitic, and these were consumed by the rats in the process of their toilet. Irradiation of the rats' total ration or of muscle, liver,[7] or vegetable oils [10] induced antirachitic properties in these substances, as evidenced by experimental work. Here, then, was part of the explanation of the identical antirachitic power of cod-liver oil and of light; the antirachitic factor which is present in cod-liver oil can be produced under the influence of ultra-violet light either in the living organism or in its foodstuffs. But so far it was not clear whether this "antirachitic factor" was a chemical entity or a form of radiant energy. Kugelmass's and McQuarrie's work,[11] suggesting that ultra-violet rays were given off by certain antirachitic substances when oxidised, has not been confirmed by other workers.[12] Now the explanation has been carried a step further. Under the influence of light two chemically pure substances, cholesterol obtained from animals and phytosterol obtained from plants, have been shown to acquire antirachitic properties,[13] and in the process cholesterol is changed in chemical constitution—in colour,[14] melting point,[15] and in its spectrum.[16] Moreover, the skin of an irradiated animal has antirachitic properties when fed to a rat on a rachitic diet.[14] Now the skin contains cholesterol (an alcohol). Cholesterol esters, formed from cholesterol and the fatty acids, are the main constituents of the secretion of the sebaceous glands. Presumably, therefore, both in the living animal exposed to ultra-violet light and in antirachitic foodstuffs, the antirachitic property resides in the cholesterol or phytosterol and possibly in other similar substances, and the animal is able to use this activated lipoid, whether it is supplied via the skin or the alimentary tract. Hess and Weinstock have demonstrated the antirachitic power of cholesterol when injected subcutaneously.[17] Ultra-violet light would seem to have no power of causing the development of fat-soluble A in the body, but only of the antirachitic factor; hence, irradiated rats given a diet deficient both in the antirachitic factor and in vitamin A only grew until their progress was arrested by the shortage of vitamin A.

### *The Authors' Observations.*

Until August, 1925, little work on the effects on man of irradiated foodstuffs had been published. Cowell [18] states that the bone lesions of two children receiving irradiated cow's milk healed more quickly than those of his control on non-irradiated milk. Steenbock and Daniels favourably influenced the calcium balance of two apparently healthy infants by giving irradiated olive oil,[19] and Hess tested on rachitic children irradiated carrots, spinach, and dried milk, but gives few details.[11] During August, however, there appeared a paper by Kramer, who showed by means of X ray photographs and examination of the blood the curative value of irradiated cow's milk on eight young children.[18]

---

* [illegible] communication was made at the meeting [illegible] Medical Association in July, 1925.

From February till July, 1925, the writers have been investigating the clinical value in the treatment of rachitic children of certain irradiated foodstuffs. The children under observation were in-patients at the Queen's Hospital for Children. All were in the same ward, which is well lighted by windows facing north and south and is well ventilated. Their ages varied from 7 months to 3½ years, and the chief facts concerning each child are summarised in the accompanying table. The diet in the main was the ordinary hospital one and varied according to the age and weight of the individual. Each child received a liberal allowance daily of full-cream dried milk (a spray process milk, Trumilk, was used); 3½ to 5 oz. were given, being equivalent to approximately eight times that amount of fluid milk. The diets were as follows:

*Diet A.*—Meat, soup, vegetables, pudding as ordinarily supplied from the hospital kitchen, bread, butter, jam, and fruit, with 3½ oz. of dried milk daily.

*Diet B.*—Soup, milk pudding, bread and butter, and 5 oz. of dried milk daily.

*Diet C.*—Dried milk, varying in quantity with the size and age of the child, sugar, and fruit juice.

The source of ultra-violet light was a mercury arc (mercury-vapour quartz lamp) of the Hanau type, made by the Hewittic Electrical Company, a vacuum lamp with a metal reflector, and a burner voltage of 140 (supply current 210 volts). In each case the food to be irradiated (24 hours supply) was placed for one hour under the lamp in a thin layer at a foot distance from the burner.

### *Results Obtained.*

1. *Control Observations.*—Throughout the period of observation there were children in the wards on the same diets, but having no part of their food irradiated; six such cases were under observation for periods of five weeks upwards. One child (Case 9, A. K., aged 3½ years) was admitted in June with the rachitic lesions already healing, and they continued to heal after admission. This case, therefore, should be excluded from the series, leaving five controls. None of these showed radiographic evidence of healing without specific antirachitic treatment (see Cases 4–8 inclusive; Case 8 is discussed in paragraph 5 below).

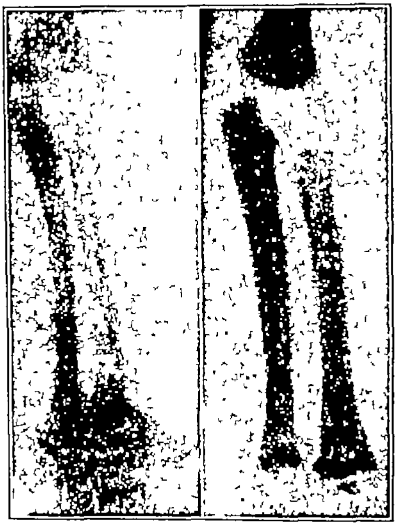
2. *Cases Treated with Irradiated Dried Milk (Rickets and Spasmophilia).*—Three children received irradiated dried milk, 3½ to 5 oz. daily. In one, the eldest, aged 3½ years (Case 1, J. E.), the milk formed only part of a mixed diet, which included meat and vegetables. All three children showed radiographic evidence of healing between the fifteenth and twenty-second day after treatment was begun (the photographs were taken at approximately weekly intervals), and in all there was steady progress in calcification. This was at a rate comparable to that usually obtained by direct exposure of the child to the light of the lamp or by administration of cod liver oil by mouth. Moreover, in one child suffering from spasmophilia (infantile tetany) the condition was cured as it would be by direct radiation. This case is one of special interest. The child (Case 2, J. L., aged 7 months) had, on admission, frequent laryngeal stridor and a well marked Chvostek reaction (contraction of facial muscles obtained by tapping the side of the face over the branches of the facial nerve). He developed pneumonia on the eighth day after admission, but this acute illness did not interfere with the cure of either his rickets or tetany. Craniotabes, which had been fairly extensive, had nearly disappeared by the seventeenth day, and all clinical evidence of spasmophilia by the eleventh to twelfth day.

3. *Cases Treated with Irradiated Dried Milk which was Subsequently Boiled.*—In order to test whether or not the antirachitic property induced by light in the milk would withstand the effects of cooking, two children were given irradiated dried milk, which, after being mixed with water, was simmered over a gas flame, the temperature being kept at boiling-point for ten minutes. Both these children (Case 4, F. B., aged 8 months, and Case 5, J. H., aged 18 months) (see Fig. 1) had undergone a preliminary control period during which there was no evidence of healing. The X ray plate showed the first signs of healing on the seventeenth and nineteenth day respectively after the boiled irradiated milk was first given. The antirachitic property thus induced will, therefore, withstand the effects of boiling.

4. *Case Treated with Irradiated Sweetened Condensed Milk.*—One child (Case 6, D. R., aged 18 months) (see Fig. 2) with severe rickets, as shown radiographically, received, after a preliminary control period, 5 oz. of irradiated full-cream sweetened condensed milk (Nestlé's) in place of dried milk. The same rapid calcification was brought about as in the five cases already described.

5. *Cases Treated with Irradiated White Flour.*—The results obtained with irradiated, white, wheaten flour were inconclusive, probably negative. The flour after irradiation was given uncooked, mixed with soup, gravy, or minced meat. It was well taken and evidently digested, since the stools showed few starch granules. E. M. (Case 7, aged 1 year 10 months) received 3 oz. daily with no evidence of healing. She was then given outdoor treatment and cod liver oil by mouth, and healing was apparent in 20 days. The other case (Case 8, V. O., aged 1 year 10 months) was admitted on Feb. 4th. On March 11th the child had a single exposure to the light of the mercury arc, and eight days later there was radiographic evidence of healing. This slight calcification appeared unusually early, but the after-history supports, though it does not prove, the view that it was due to the exposure to the mercury arc. From March 26th to June 18th the child was given 3 oz. of irradiated flour daily, but after very slow progress for about a month showed little or no advance in calcification, until given outdoor treatment in June. There seems no doubt that the antirachitic power induced in the flour was feeble, if present at all.

FIG. 1. (*Case 5.*)



Moderate rickets—active. Radiogram taken April 8th, 1925.

Bone lesions healed after 3 months' treatment with irradiated dried milk which had been boiled for 10 minutes after irradiation. Radiogram taken Sept. 7th, 1925

6. *Case Treated with Irradiated Cotton-seed Oil.*—Only one in-patient (Case 10, F. S., aged 15 months) received irradiated cotton-seed oil. He was given on the first day 1½ drachms, increasing by the seventh day to 6 drachms daily, the amount being given in three doses. Healing was apparent on the thirty ninth day and progress in calcification was slow. Six drachms must be considered near the limit of tolerance for a young child, since this amount set up diarrhœa in several out-patient children receiving it. Taking this case in conjunction with the out-patients under observation, it is safe to say that the irradiated cotton-seed

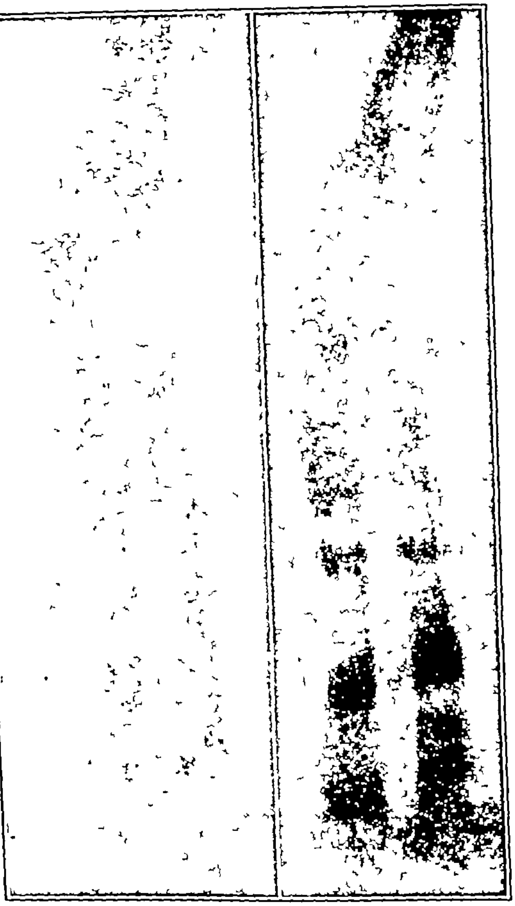
rtainly had not the potency of an average sample of d-liver oil, but it would seem probable that 6 drachms ercised some curative effect, though more observations in-patients would be necessary to establish this point.

*Comments.*

Experiments on rats have shown that both white our and cotton-seed oil *can* be activated by irradiation nd that a very small quantity (0·1 c.cm.) of the latter will exert a protective influence on rats on a rachitic diet.[20] The failure to obtain similar results with children may be due to the fact that the substances in the quantities given were ineffective, or only slightly effective, or that we overshot the mark by too prolonged irradiation. It has been shown that ultra-violet light first activates olive oil (half to five hours' exposure) but that prolonged exposure (e.g., ten hours) destroys this antirachitic power.[21] A similar effect has been obtained by Hess with pure cholesterol[14] which he found inert after four hours' exposure to the mercury arc, and prolonged exposure (17 hours) has rendered cod-liver oil inactive.[21] On the other hand, Steenbock and Black found cholesterol still active after 17 hours' exposure to the mercury arc,[21] a fact probably to be explained by the varying in of the lamps used. Hess states that two ure to the mercury arc at one foot tivated linseed oil.[20]

ossible to say from the small number of eated whether the improvement in the general health obtained by giving irradiated milk is comparable with that obtained by giving artificial light treatment or only with that obtained by the administration of cod-liver oil, for in cases of rickets the effect of a therapeutic agent on the general health and on calcium metabolism does not necessarily show a parallel course. Light therapy usually improves the child's activity, muscle tone, and general contentment, in addition to bringing about normal calcium metabolism; whereas cod-liver oil administration brings about normal calcium metabolism, but has much less effect on the general health. Conversely improvement of the general health is not necessarily accompanied by healing of the bone lesions.

FIG. 2. (*Case 6.*)



Severe active rickets. Radiogram taken July 15th, 1925. Bones were unchanged after 2 months' in hospital, in spite of good general progress.

Bone lesions nearly healed after 2 months' treatment with irradiated sweetened condensed milk. Radiogram taken Sept. 7th, 1925.

It would, however, seem reasonable to suppose that the effect in rickets of foodstuffs artificially rendered antirachitic by ultra-violet radiation would be identical with that of naturally occurring antirachitic substances, such as cod-liver oil. It is clear that many of the physiological effects of light—for instance, erythema of the skin and pigmentation, to take the most obvious examples—cannot be brought about by a foodstuff endowed with antirachitic properties.

*Summary of Results.*

Observations were carried out on the effect on rachitic children of foodstuffs irradiated for one hour at one foot distance from a mercury arc; 24 hours supply was radiated daily. Weekly X ray photographs were taken of the long bones of the children and the results were based on changes in the rachitic bone lesions as shown by the X ray plate.

(*a*) Five control cases not healing on admission showed no healing without specific antirachitic treatment. All were given full-cream dried milk.

(*b*) The following cases showed calcification of the bones at a rate comparable to that usually obtained by direct radiation or by the administration of cod-liver oil: Three children given 3½ to 5 oz. of irradiated full-cream dried milk. One child given irradiated sweetened condensed milk. Two children given irradiated dried milk which had been boiled for ten minutes after irradiation.

(*c*) Two children were given 3 oz. of irradiated white flour. One gave a negative result, the other result was inconclusive, probably negative.

(*d*) One child was given 6 drachms of irradiated cotton-seed oil. There was very slow healing of the bone lesions.

(*e*) One child suffering from infantile tetany was cured by irradiated dried milk.

*The Future Value of Irradiated Foodstuffs.*

Animal experiments have shown that two minutes' irradiation will activate linseed oil,[20] and that irradiated olive oil can be kept for at least a period of ten months,[11] and linseed oil six months,[20] and still possess antirachitic power. There is little doubt that when it becomes possible certain foodstuffs will be irradiated on a commercial scale. This cannot be done at present as, in order to prevent undesirable exploitation, the process has been protected by a patent, as was done in the case of insulin. Among the substances activated in greater or less degree by different workers are muscle, liver, skin, milk, butter, lard, egg yolk, crude casein, yeast, a variety of vegetable oils, including olive oil, coconut oil, cotton-seed oil, linseed oil, and corn oil, as well as various cereal substances, including wheat, wheat flour, Indian corn, corn starch, and rolled oats. It is obvious that only foodstuffs with keeping properties are likely to be treated on a large scale. The use of these by the greater public will depend largely on their price, and, for all but infants, on their taste. Few adults like the taste of dried milk, and, in the writers' opinion, irradiation for an hour makes it less palatable. The taste is changed even after two minutes' exposure at one foot from the mercury arc. If such a very short exposure will activate foodstuffs, the cost should not prove an obstacle. For premature infants and for those of poor digestive power it would be an undoubted

### SUMMARY OF CASES TREATED WITH IRRADIATED FOODSTUFFS.

| Case. | Age on admission (years). | Diet. | Control period in 1925. | Date treatment begun. | Nature of treatment. | Date radiographic healing observed. | General health. | Bone lesions as shown radiographically. |
|---|---|---|---|---|---|---|---|---|
| 1 J. E. | $3\frac{1}{12}$ | A | 28/1 to 13/2 | 13/2 | Irrad. dried milk. 3½ oz. daily. | 28/2 (15th day) | Feeble and flabby on admis. Just able to sit up. Marked kyphosis. Massage; improved greatly. Gained 3½ lb. in 2½ months. | Severe rickets. Good progress. Discharged healed in 2½ m. |
| 2 J. L. | $\frac{7}{12}$ | C | — | 17/3 | Irrad. dried milk. 4½ oz. daily. | 7/4 (22nd day) | Admitted with spasmophilia (laryngeal stridor) and craniotabes. Pneumonia 3 days later. No stridor or Chvostek after 11th to 12th day. Good gen. progress. Gained 1½ lb. in 1½ m. Craniotabes nearly disappeared by 17th day. | Mod. rickets on admis. Nearly healed in 6 weeks. |
| 3 W. S. | $\frac{9}{12}$ | B | — | 17/2 | Irrad. dried milk. 5 oz. daily. | 5/3 (17th day) | Under weight; gen. condition good. Gained 1½ lb. in 1½ m. | Slight rickets, nearly healed in 30 days. |
| 4 F. B. | $\frac{6}{12}$ | C | 21/3 to 5/5 | 5/5 | Boiled irrad. dried milk 4½ oz. daily. | 21/5 (17th day) | Pale child. Poor gen. progress in hosp. | Very slight rickets. |
| 5 J. H. | $1\frac{4}{12}$ | B | 13/4 to 5/6 | 5/6 | Boiled irrad. dried milk 5 oz. daily. | 23/6 (18th day) | Small, fat, rather flabby on admis. Satisfactory progress. Gained 3 lb. in 3½ m. (1½ lb. in 1½ m. control period). | Mod. rickets. Good progress with treatment. Nearly healed in 2 m. (See Fig. 1.) |
| 6 D. R. | $1\frac{6}{12}$ | B | 14/5 to 7/7 | 7/7 | Irrad. sweetened condensed milk. 5 fluid oz. daily. | 28/7 (21st day) | Small, but gen. condition fairly good on admis. Gained 2½ lb. in 3 m. (1½ lb. in 1½ m. control period.) | Severe rickets. Good progress with treatment. Nearly healed in 2 m. (See Fig. 2.) |
| 7 E. M. | $1\frac{10}{12}$ | B | 11/3 to 8/5 | 8/5<br>18/6 | Irrad. flour 3 oz. daily. Outdoor and cod-liver oil. | No healing<br>7/7 (20th day) | Fair condition on admis. Gained nearly 1 lb. control period. No gain in weight while having irrad. flour. | Slight rickets. No healing with irrad. flour for 42 days. Advanced healing after 4½ weeks' treatment with sunshine and cod-liver oil. |
| 8 V. C. | $1\frac{10}{12}$ | A | 4/2 to 11/3 | 11/3<br>20/3<br>18/6 | Single exposure to light of mercury arc.<br>Irrad. flour 3 oz. daily. Outdoor. | 18/3 (8th day) | Small, but well nourished on admis. Poor gain in weight in hosp. | Mod. rickets. 4/2 to 11/3, no healing. 18/3 to 28/4, very slow progress. 28/4 to 1/7, stationary. 15/7, advanced healing (1 m. out of doors). |
| 9 A. K. | $3\frac{6}{12}$ | A | 3/6 to 2/7 | 2/7 | Outdoor. | Healing on admis. | Small and backward, but well nourished and good colour. Gained 3 lb. in 1½ m. in hosp. | Severe rickets. Steady progress. |
| 10 F. S. | $1\frac{9}{12}$ | B | — | 21/1 | Irrad. cotton-seed oil 1½ dr. increasing to 6 dr. daily by 7th day. | 2/3 (39th day) | Fat, flabby child. Gained 3½ lb. in 2 m. in hosp. | Slight rickets. Slow progress. Nearly healed after 2 m. treatment. |

advantage to be able to give a milk preparation of good antirachitic potency. At present it is certainly desirable to give every artificially fed infant and many breast-fed infants cod-liver oil daily all through the winter, since ordinary foodstuffs, even breast milk, will not ensure protection to an infant living an indoor life and consequently getting very little ultra-violet light.[22] An inexpensive antirachitic dried milk would have obvious advantages over daily cod-liver oil medication. Its use would, generally speaking, be required only in winter, since in London, for example, it is our experience that it is rare to find a case of active rickets in the late summer on any diet, as by that season increased exposure to light out of doors has established the normal process of calcification of the bones.

The authors, in conclusion, would like to place on record their gratitude for the constant help and coöperation they have received from colleagues in both the medical and nursing professions. Their particular and very sincere thanks are due to Sister F. Francis, who was responsible for the entire series of X ray photographs, to the ward sister, Sister D. I. Hook, and to Sister M. W. Westbrook, who daily carried out the irradiation of the foodstuffs.

# ULTRA-VIOLET IRRADIATION IN THE ACTIVATION OF CHOLESTEROL AND FOODS.

BY ALFRED F. HESS, M.D.,
AND
MILDRED WEINSTOCK, B.S.

*(From the Department of Pathology, College of Physicians and Surgeons, Columbia University, New York.)*

IT is thoroughly established that animals as well as infants can be protected from rickets by means of the ultra-violet rays from the sun or mercury-vapour or carbon-arc lamps. It has been shown also by several investigators that under certain conditions growth can be brought about in animals by subjecting them to these rays. A year or more ago Hume and Smith[1] reported that they were able to stimulate growth by keeping rats in an atmosphere which had been irradiated with ultra-violet rays. These experiments, however, have not been corroborated. Webster and Hill,[2] in a paper entitled the Supposed Influence of Irradiated Air on Growth, recently reported negative results. This likewise was our experience in tests of this kind carried out about two years ago.

### *Effect of Irradiation of Inert Oils.*

In view of the remarkable effect of the solar rays on vegetable life, it occurred to us to ascertain whether the irradiation of inert vegetable substances could endow them with antirachitic properties. With this end in view, we irradiated various fluids with the ultra-violet light from a mercury-vapour quartz lamp. In June, 1924, we communicated to the American Pediatric Society[3] a preliminary report of these experiments, which may be summed up by the statement that vegetable oils which are ordinarily inert were found to have developed marked antirachitic activity following irradiation. The oil used in these experiments were cotton-seed and linseed oils, which were exposed in Petri dishes in very thin layers. Soon after this communication Steenbock and Black[4] reported similar results with irradiation of various foods. More recently these experiments have been corroborated by Webster and Hill.[5]

During the past year this work has been continued and extended in various directions.[6] It was found that the irradiated vegetable oils maintained this acquired potency for a very long period. Recently we tested cotton-seed oil that had been irradiated one year ago and kept ever since under ordinary conditions in a stoppered bottle, and found that 0·1 c.cm. sufficed to protect rats which were placed on a stringent rickets-producing diet. Growing wheat, whether green or ætiolated, was activated in this manner, as were green or yellow lettuce leaves. Chlorophyll seemed to play no rôle in this activation; indeed, an attempt to activate solutions of chlorophyll consistently failed. Among other substances which could not be activated by these radiations may be mentioned hæmoglobin, cream, phosphatide of yolk of egg, glycerol, and gelatin. Oxygen seemed to play little or no part in this process, as the change was found to take place in an atmosphere of nitrogen. On the other hand, refined wheat flour readily underwent activation, as did dry milk powder. Recently dried milk which had been irradiated three months ago was again tested and found to be active; 5 per cent. of this dried milk powder substituted for an equivalent amount of the flour in the standard rickets-producing dietary was sufficient to render it a markedly rickets-protective, instead of a rickets-producing, ration. In this connexion it is of interest to note that Cowell,[7] in a recent paper entitled Irradiation of Milk and the Healing of Rickets, reported favourable results in the treatment of animals with irradiated fluid milk. Kramer likewise has reported favourable results with irradiated fluid milk in the cure of infantile rickets.[8]

As it has been repeatedly shown that the active principle of cod-liver oil is present in its non-saponifiable and absent in its saponifiable fraction, it was interesting to ascertain whether this same relationship held true for activated vegetable oil. Without entering into the technical details of this experiment, which may be found elsewhere, it may be stated that fractionisation showed that the active principle is present only in the non-saponifiable moiety of the irradiated oil, the other fraction being apparently as inert as ordinary oil which has not been irradiated.

### *Antirachitic Potency Conferred by Irradiation.*

In January of this year we communicated the results of a series of experiments[9] which showed that the phytosterol obtained from these oils, although unable to protect against rickets, can in the same way be endowed with antirachitic potency, and, furthermore, that irradiation experiments carried out with purified cholesterol gave the same result (Table I.).

* 1 per cent. in water.

For these experiments the cholesterol was irradiated either dry or suspended in water, and was fed to the rats usually in a dosage of 0·1 c.cm. daily of a 1 per cent. suspension. Shortly thereafter the results of further experiments with irradiated cholesterol were communicated. It was found that activated cholesterol is able to exert its protective effect, not only when it is given by mouth, but likewise when it is suspended in water and injected subcutaneously in small amounts. This result will have to be studied further, in view of the fact that cod-liver oil is supposed to be of little or no value when given by this method. A series of tests with selective filters brought out the additional fact that the radiations which render cholesterol active biologically are similar in wave-length to those which we had previously found to be protective when animals were exposed directly to the rays. In general, it may be stated that these effective wave-lengths are about 300 μμ, and that ultra-violet radiations longer than 313 μμ, as well as all the visible rays of the spectrum, have no power whatsoever to bring about this alteration.

It has been shown by various investigators that rickets can be developed in rats as the result of placing them on diets either low in phosphorus or low in calcium. The microscopic picture of the bones is somewhat different according to which of these rations is fed. It was found that irradiated cholesterol is effective in preventing rickets occasioned by either of these deficient diets—whether low in phosphorus or low in calcium.

### *Activation of Cholesterol.*

These experiments with cholesterol have been recently confirmed by various investigators. Drummond and his co-workers[10] obtained similar results with irradiated cholesterol obtained from brain or from cod-liver oil. Rosenheim and Webster[11] activated cholesterol dissolved in liquid paraffin. By these methods they seem to have been able to reduce the required protective dose to less than 1 mg. Very recently Webster and Hill,[4] in an article on the Causation and Prevention of Rickets, state that "further investigations show that cholesterol or a vegetable sterol after radiation has very great antirachitic power." It seems evident, therefore, that there can be no doubt regarding the fact that either phytosterol or cholesterol can regularly be activated by means of ultra-violet irradiation.

As far as we know, there have been no previous experiments on the effect of ultra-violet rays on these sterols. Some years ago Ritter[12] observed that preparations of cholesterol, prepared some 25 years previously, had become yellow in colour during this interval. He writes that "the preparation had stood in glass-stoppered closed bottles in a glass cupboard." A few years later Schulze and Winterstein[13] reported that they had kept some cholesterol for two years between watch-glasses, and that it had become yellow and its melting-point had fallen from 116·5° to 135°. Some cholesterol, which had been stored for the same length of time in a test-tube in an atmosphere of carbon dioxide, showed a lowering in the melting-point of only 1°. Their conclusion was that the alterations were probably an oxidation effect occurring in association with light. These changes in cholesterol can have nothing in common with the activation which we are considering. The fact that the change took place while the cholesterol was in glass bottles and in a cupboard eliminates this possibility, for, as is well known, the radiations which are able to traverse glass are inert in relation to rickets. Our experiments have shown that when cholesterol is activated by means of ultra-violet light its melting-point is but little altered and that it does not change in colour. It is only after it is irradiated for long periods, for six or eight hours or longer, that its melting-point falls and that it begins to develop a yellow tint. But when such chemical and physical changes are brought about it is found that the cholesterol is not active, that the prolonged irradiation has caused it to pass through the stage of activation into one of de-activation. After the irradiation has been maintained for a period of 24 to 48 hours the cholesterol acquires a canary yellow colour, and its melting-point drops to a point similar to that reported by Schulze. It may be added that animal tests have shown that cholesterol which has been de-activated by means of prolonged irradiation cannot be reactivated by the ultra-violet rays; the reaction is not reversible.

These biological experiments were confirmed by means of spectral absorption tests, in which the cholesterol was dissolved in alcohol and illuminated by means of the mercury-vapour lamp. These tests showed that activated cholesterol absorbs ultra-violet radiations to a less degree than does ordinary cholesterol, an effect which is intensified to a certain extent with increasing amounts of irradiation. If, however, irradiation is prolonged for many hours the activated cholesterol becomes even less transparent than non-irradiated cholesterol. Visible light, radiant heat, and Röntgen rays do not alter the absorption spectrum of cholesterol. It is unnecessary to give in detail the result of these experiments as they have been reported elsewhere.[9] They are mentioned merely to emphasise the fact that they confirmed in all respects the biological tests which were carried out on rats. The fact that spectral absorption was altered in the course of activation would seem to indicate that the change is of a chemical rather than of a physical nature. In this connexion it may be added that attempts to concentrate the active fraction of irradiated cholesterol proved abortive, and that successive fractions which were obtained in this way were found to be less active, rather than more active, when tested biologically or by the spectral absorption method.

In view of the fact that ultra-violet rays are specific in the therapy of rickets, and that these radiations do not penetrate the skin, an experiment was devised to determine whether the skin itself could be activated after having been removed from the body. Skin is particularly rich in cholesterol; in fact, no other organ except the brain contains a greater total amount of this substance. It seemed, therefore, probable that the cholesterol in the epidermis would respond to irradiation. To this end human skin and calf skin were irradiated and fed daily in 1 g. per capita amount to rats which were receiving a low phosphorus diet. The control series received non-irradiated skin. As will be seen in Table II., the rats which received the irradiated skin were regularly protected from rickets, whereas the control animals developed rickets; the inorganic phosphorus of the blood followed a parallel course. This result is of interest in connexion with the recent experiments of Luce,[14] who found that "exposure to sunlight appears to have a small effect in determining the antirachitic value of the milk" of the cow.

* Microscopic, Nil.

It would seem quite possible that the cholesterol in the skin is normally activated and rendered antirachitic by ultra-violet irradiation, that the solar rays and similar artificial radiations are able to bring about this conversion. This point of view regards the superficial skin as an organ which reacts to particular light waves (the epidermal organ) rather than as a mere protective covering.

### *Application to Practical Dietetics.*

The remarkable antirachitic potency which has been brought about in cholesterol and in vegetable and animal foods by means of artificial irradiation naturally suggests an application of this procedure to practical dietetics. Table III. illustrates the results obtained in cases of rickets by giving irradiated foods or cholesterol. It will be noted that the best result was obtained with irradiated dried milk. This milk was irradiated in thin layers for a period of half an hour with the lamp at a distance of 1 foot.

In regard to the spinach, which is recorded in the table, and which was found to have acquired antirachitic properties, it should be added that it was cooked for half an hour subsequent to having been irradiated, and that this process did not seem to have affected its activity. A test was carried out also with cholesterol. This cholesterol was irradiated in the dry state for half an hour with the lamp at a distance of 1 foot, and was at once incorporated in cotton-seed oil to the extent of 3 per cent.

TABLE III.—*Treatment of Rachitic Infants with* IRRADIATED FOODS (*March*).

| 2 | 13 | | 3·3 .. 5·1 | Healed. |
| 3 | 9 | | 2·4 .. 4·8 | Mod. healing. |

An extensive series of experiments had developed the fact that cholesterol which had been irradiated by ultra-violet rays readily lost its acquired activity when kept either in a dry state or suspended in water, but that it did not undergo this "ageing process" when dissolved in oil. Irradiated cholesterol, when given in oil in a dosage of two teaspoonsful daily, brought about definite improvement in the course of four weeks. It is premature to discuss whether the antirachitic action of irradiated cholesterol is comparable to that of ultra-violet rays or to cod-liver oil. Recent experiments would tend to indicate that larger doses are of advantage. However, the established fact that foods, as well as cholesterol and phytosterol, can be endowed with specific antirachitic potency has, quite apart from any clinical application, a definite theoretical interest and value. It furnishes a chemical basis for interpreting the remarkable action of ultra-violet irradiation in rickets.

At the present time it is difficult to state the relationship between activated cholesterol and the vitamins. The definition of a vitamin is so vague that there may well be a difference of opinion as to whether one should consider that a vitamin has been elaborated by means of irradiating cholesterol. It is true that the amount of irradiated cholesterol which is needed for protection or cure is of the magnitude which we are accustomed to associate with the vitamins. This question, however, has now advanced beyond the phase of biology into the sphere of chemistry, and judgment must be deferred until the subject has been elucidated by chemical investigation.

# ISCHÆMIC NECROSIS OF THE CARDIAC WALL.[1]

BY CAREY F. COOMBS, M.D., F.R.C.P. LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS TO THE BRISTOL GENERAL HOSPITAL;
AND
GEOFFREY HADFIELD, M.D., M.R.C.P. LOND.,
PATHOLOGIST TO THE HOSPITAL.

(*With Coloured Plate.*)

SUDDEN or rapid occlusion of a larger branch of one of the coronary arteries of the heart by thrombosis or (much less often) by embolism initiates a certain series of symptoms which it is convenient to group under three heads: (*a*) acute ventricular failure, (*b*) chronic cardiac failure, and (*c*) death before diagnosis.

### *Cases with Acute Ventricular Failure.*

The largest group is that fully described in recent years by American physicians. Our experience of these has differed from theirs in that we have not seen a necropsy in a case of this kind. Possibly the fact that hospital patients in America come from a less restricted social stratum than in this country may account for the difference. Anginal symptoms are much more often encountered in private than in hospital patients in this country. Our own experience of this category of symptoms, embracing about a dozen cases, all of which, save one, arose in men, and all in persons of 60 or more, has been drawn exclusively from private practice. The following note of one of these histories embodies most of the points to which we need draw attention.

The patient, a medical man of 62, had for some long time been known to have a high blood pressure. For a year, on and off, he had been troubled by præcordial pain. The night before he was first seen by one of us (C. F. C.) he had a very severe attack of this pain, the worst he had ever experienced. He gave himself ¼ gr. of morphine and used a boxful of amyl nitrite capsules without any relief; this he finally secured by administering chloroform to himself by inhalation. When seen he was orthopnœic, pallid, and sweating. He had a wide, feeble impulse, triple rhythm, and an alternating pulse. Two days later the pain had quite gone, but there was tenderness over the præcordia, the pulse still alternating, its rate 116 per minute, and there was a characteristic pericardial to-and-fro rub over the area of cardiac impulse, with râles at the bases. Seen again that night, he appeared to have a totally irregular pulse, but no record could be made. Next day this arrhythmia had gone, but the pulse was still alternating. He improved for a few days, then died suddenly in the night.

Some of our patients have died in the attack; others have survived for days or weeks in a precarious state of collapse, punctuated and aggravated by recurrence of the initial symptoms. There is often slight fever for the first few days. The patients have been so ill that it has, unfortunately, been impossible to get any electrocardiograms.

### *Cases with Chronic Cardiac Failure.*

In this class the patient survives longer, possibly because the arterial occlusion is less rapidly consummated. The symptoms are well illustrated by the following history.

A woman of 39 was well till January, 1922, when she had "influenza." In the following month she had attacks of paroxysmal dyspnœa with vomiting. Ever since then she had been orthopnœic, with loss of flesh. When seen by one of us (C. F. C.) she had a pulse of 108 to the minute, which alternated; a blood pressure of 140 mm. Hg systolic and 120 diastolic; a diffuse impulse, its area being increased to the left; and a bruit de galop. She was very œdematous as high as the waist. Death ensued about three months after the onset.

*Post-mortem.*—The territory of the anterior descending branch of the left coronary artery was extensively fibrosed, white, and tendon-like. A thin line of muscle and an intact endocardium covered it internally; its pericardial

---

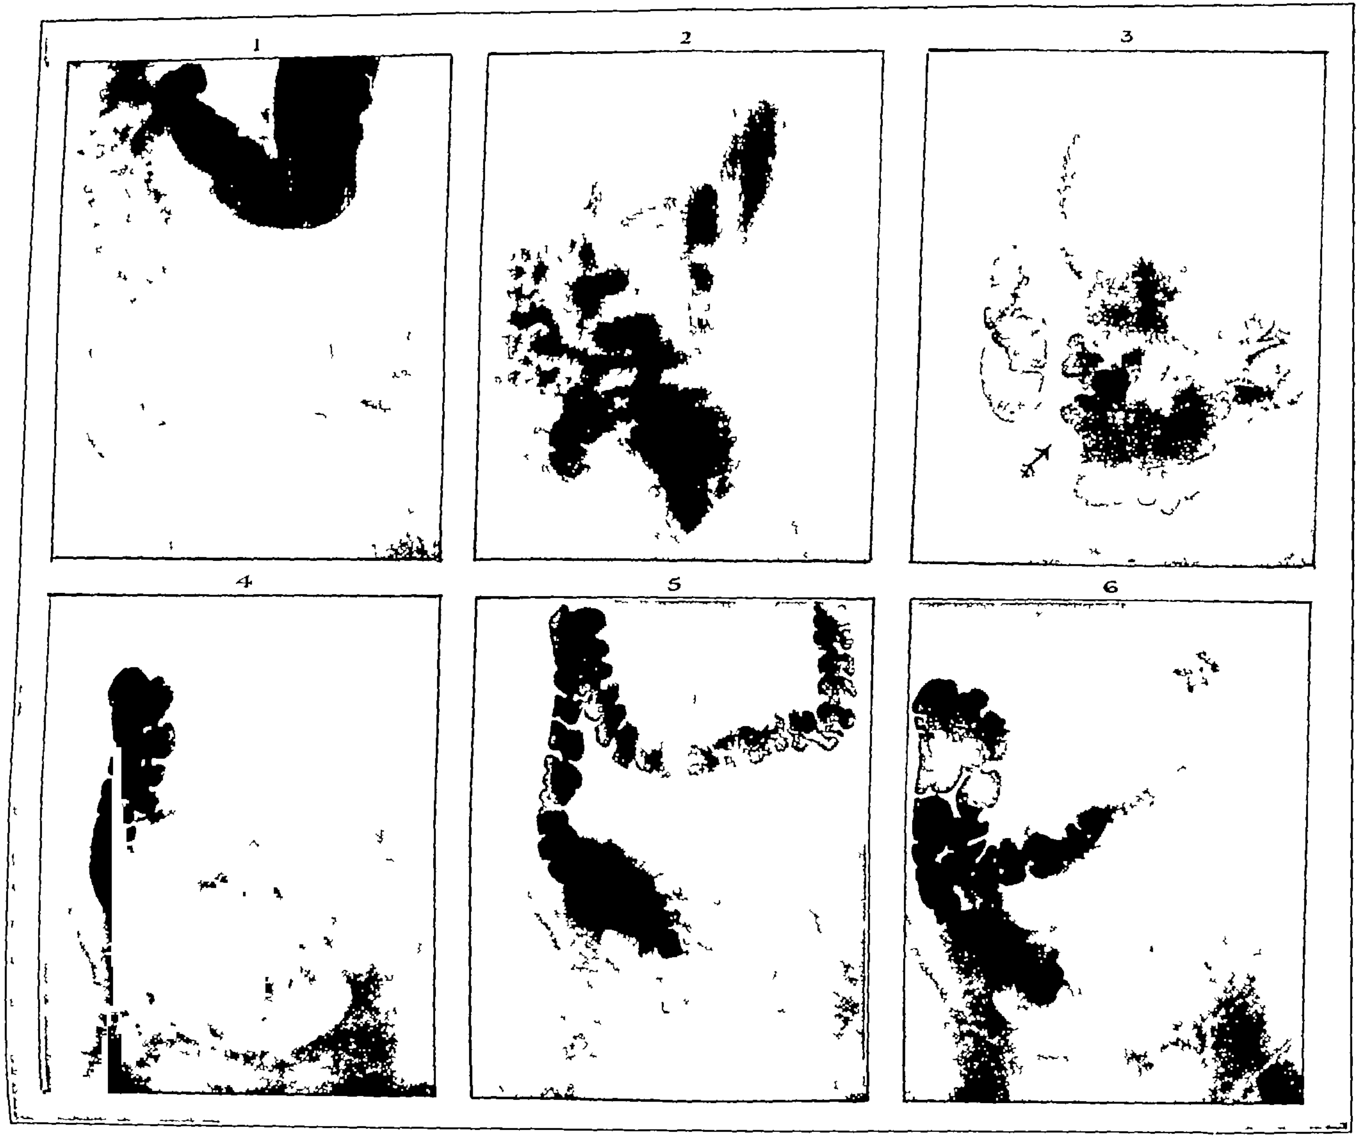
DR. T. I. CANDY: INCOMPLETE INTESTINAL OBSTRUCTION.



surface was not adherent. The fibrosed muscle was slightly stretched and the lesion formed an ill-defined pouch. There was no suggestion of recent infarction. The anterior descending branch of the coronary artery was obliterated at its origin in the auriculo-ventricular groove, apparently by old thrombosis. Arterio-sclerosis was slight in the other coronary vessels.

### *Cases with Unrecognised Symptoms.*

In this group the patient dies of symptoms, the nature of which is not realised during life.

The coloured plate (for which we are indebted to Miss Pillers) accompanying this note represents the heart of a man of 40 who was sent up to the ward, seen by one of us (C. F. C.) at the end of a round, and put to bed for detailed observation. He said that for about a year he had had pain under the sternum on exertion. About a week before admission, his own doctor had seen him and diagnosed influenzal pneumonia, but had remarked the disproportionate severity of his dyspnœa. When admitted he was pale and very dyspnœic, but able to talk cheerfully and even to joke about the prospect of an early return to work. There were râles all over both chests, and in retrospect it seems that the heart sounds must have been weak, but at the moment no physical signs of cardiac disease were noted and the presence of a serious heart lesion was barely suspected. He became rapidly worse and died that night.

*Post-mortem.*—Extensive, massive, and recent infarction of the heart wall was present at a stage rarely found at autopsy, the mass of opaque, yellow and necrotic muscle being still in situ, and its irregular sinuous edge clearly marked out by a thick line of congested arterioles. The area of ischæmic necrosis is indicated in the diagram; it did not correspond exactly with the territory of the occluded vessel and (as is usual) the deep central layers of the muscle were most affected. Typical gummatous aortitis was present, and one lung presented the naked-eye picture of pneumococcal lobar pneumonia, such as is seen about the fourth to the sixth day. The myocardial infarction and the pneumonia were of approximately the same age, and it is tempting to assume that they were related, the acute pulmonary infection being the immediate cause of the recent obliteration of an artery already narrowed by syphilitic infection.

In this category also should be included cases the symptoms of which are apparently abdominal.

---

# A RADIOLOGICAL STUDY OF A CASE OF INCOMPLETE INTESTINAL OBSTRUCTION.

BY T. I. CANDY, M.B., B.CH. BELF.,
D.M.R.E. CAMB.,
HON. RADIOLOGIST TO THE ROYAL GWENT HOSPITAL, NEWPORT, MON

(*With Illustrative Plate.*)

THE accompanying illustration of a series of six bismuth-meal skiagrams will be of interest as a radiological study of obstruction of the intestinal tract and as an example of modern radiographic technique. A short account of the clinical course of the case is given from the surgical and pathological points of view.

The skiagrams were taken at the following intervals after ingestion of the bismuth meal, all in the prone position: (1), 5 minutes; (2), 3 hours; (3), 6 hours; (4), 12 hours; (5), 24 hours; (6), 36 hours. (See plate.)

For the information of those interested in the technical side, the following are the exposure data which were the same for each skiagram: Exposure time, 1 second; spark-gap, 5 inches; milliampèrage, 40 ma.; focal film distance, 30 inches; instrument, 10 K.V.A. transformer; tube, standard Coolidge; screens, double intensifying; film, 15 by 12, Eastman dupli-tized, ordinary.

Another no less important factor in the attainment of the uniform result was the dark-room technique, which was carried out strictly in accordance with the directions of the makers of the dupli-tized X ray film —namely, development for a standard time of five minutes, with a standard developer formula, at a standard temperature of 65° F.

### *History of the Case.*

The patient, a woman, aged 47, was admitted to the surgical wards of the Royal Gwent Hospital, under Mr. Morrell Thomas, in January, 1923. She complained of constant abdominal pain more or less in the region of the umbilicus and right iliac fossa, but not very definitely localised. There was deep tenderness over the ileo-cæcal region. The symptoms dated back for 12 years. Appendicectomy had been performed ten years previously, which gave temporary relief. The symptoms recurred about six months afterwards, at first in a mild form, but gradually getting worse. For the past two years she had been a complete invalid with abdominal pain. Vomiting was an occasional symptom but not a frequent one. She always suffered greatly from constipation. She was losing weight, and said she was only a shadow of her former self. Weight on admission, 7 st. She had been in several hospitals, but a second operation had not been undertaken. She had not previously had a bismuth-meal X ray examination.

### *X Ray Examination Report.*

Retention in stomach after six hours. Definite ileal stasis and marked dilatation of the coils of the jejunum, showing prominently the valvulæ conniventes. There is narrowing of the terminal few inches of the ileum, causing a partial obstruction (Fig. 3) and stasis in the large bowel.

### *Operation.*

Laparotomy was performed by Mr. Thomas in February, 1923. The terminal 6 inches of the ileum along with its mesentery were found to be thickened and indurated. Mr. Thomas described it as resembling the appearance and feel of a "leather-bottle stomach." The part was excised, including the thickened mesentery, and ileo-cæcostomy was performed. After the first week the patient began to gain strength. All symptoms gradually disappeared, and she was discharged from hospital "cured" on March 17th, 1923.

### *Pathological Report.*

Dr. H. W. Catto, hon pathologist, reported as follows on the excised specimen:—

*Naked-eye examination.*—The intestinal wall is thickened and the lumen narrowed with the mucous membrane thrown into folds. The mesentery attached to this portion is half an inch thick and is leathery to the feel.

*Microscopic examination.*—There is no new growth, either innocent or malignant, no specific inflammation, either tuberculous or syphilitic, and no degenerative changes. The thickened mesentery is due to a copious deposit of fat which also spreads over the bowel. The musculature of the intestine is hypertrophied, indicating that it had difficulty in doing its work. It would seem that the lipomatosis impeded peristalsis, causing hypertrophy and spasm of the muscle tissue, causing the latter to act as a pylorus tonically contracted so that the lumen was narrowed and the symptoms of obstruction arose.

### *Present Condition.*

Being interested in the after-history of the case I recently wrote asking the patient to come to hospital and report upon her present condition. She said she no longer suffered from any of the old symptoms and was in excellent health and able to carry out her household duties in a manner she had not done for years. She had excellent appetite and slept well. She said, however, that she had had occasional bouts of diarrhœa lasting a few days which had been troublesome for some months after the operation, but that she was being troubled less and less with this symptom. She looked in excellent health and had gained nearly 2 st. in weight.

### *Observations.*

In all probability this peculiar pathological condition was present ten years ago when appendicectomy was performed and was overlooked at the time of the operation, but the question is if X ray examination had been carried out at that time would it have detected the nature of the trouble and localised the seat of obstruction so definitely as it did ten years after? The answer in all probability is no, because the condition was more advanced when the present X ray examination was made, and radiographic technique has advanced considerably during that period.

I wish to acknowledge my indebtedness to Mr. Thomas for his kind permission to make use of the clinical notes of the case, and to Dr. Catto for permitting me to publish his pathological observations.

# BOROCAINE:

## A NEW LOCAL ANÆSTHETIC.

By E. WATSON-WILLIAMS, *M.C.*, Ch.M.,
F.R.C.S. Edin.,
CLINICAL LECTURER IN LARYNGOLOGY AND OTOLOGY,
UNIVERSITY OF BRISTOL.

Borocaine is announced, in the terms invariably employed for any new local anæsthetic, as possessing negligible toxicity and high anæsthetic efficiency. These two properties represent the fundamental criteria for estimating the utility of a new drug of this class. The value to clinical users of observations on these matters depends largely on the fidelity or otherwise with which clinical conditions can be reproduced.

### *Toxicity.*

In measuring toxicity we are compelled to rely on animal experiments, trusting that the information they give will be reflected in clinical practice. The points that have appeared to the author to demand attention, if our results are to be really helpful, can be summarised as follows :—

1. Subcutaneous injection of the drug affords the only method of administration which corresponds to clinical usage, and at the same time permits accurate measurement of the dose. A constant site of injection is necessary.
2. Since clinically only dilute solutions are injected, the greatest practicable dilution of the drug should be employed. This materially affects some drugs, but not all. Literally to use clinical dilutions is not practicable.
3. The same volume of diluent, approximately, should be used for the critical dose of each drug.
4. Apes are too expensive to use. Mice, rats, rabbits show a considerable tolerance to drugs of this class. Cats, dogs, guinea-pigs afford a useful compromise, having a susceptibility not much less than man.
5. The fraction of the fatal dose that will give convulsions is different with each drug. The minimal lethal dose affords essential information, and a measure of toxicity applicable to all drugs; and should be our standard of toxicity.
6. Finally, our deductions must be "fair"; for example, if we are dealing with drugs of very varying alkaloid content, we should emphasise the fact to avoid the chance of the general reader being misled.

Guided by these considerations, experiments were carried out with guinea-pigs, carefully chosen for uniformity. The greatest practicable dilution is one that gives a volume of 5 to 10 c.cm. for the minimal lethal dose in a guinea-pig of 500 g. (called the "standard dose"). The author had prepared a quantity of ethocaine borate before the drug was commercially available; this had a melting point 166° C.; and gave a pH between 8·0 and 8·5. Borocaine E was also kindly supplied by the manufacturers. The following is an abridged protocol of a typical experiment:—

No. 271.—Weight, 141 g. Injection of 5·50 c.cm. of borocaine E solution, 5 per cent. at 11.44 A.M., 15/10/25.

| Minutes. | |
|---|---|
| 12 .. .. | Dazed, quiet. |
| 17 .. .. | Falls over, head retraction. |
| 25 .. .. | Severe general convulsions. |
| 41 .. .. | Gasping, feeble movements. |
| 76 .. .. | Feeble scratching, cannot rise. |

The animal was nearly, but not quite, recovered when chloroformed at 5 P.M.

Dose: 275 mg.–620 mg. per kilo.

The results of a series of experiments are summarised in Table I.

From Table I. we see that though the toxicity of ethocaine borate is much less than that of cocaine, it is a measurable quantity. It is to be noticed that the concentration of ethocaine in the two series, as hydrochloride and as borate, was almost identical; that the dilution of drug was again the same; and that *the toxicity of ethocaine is the same whether it is gi*[illegible] *as hydrochloride or as borate.* The apparent [illegible]e between the two salts is to be attributed [illegible]eat difference in their alkaloid content.

TABLE I.

| Drug. | Concentration of solution. | Alkaloid content of— | | Dose survived, in gm./kilo. | Minimal lethal dose in gm./kilo. | Volume of standard dose c.cm. | Lethal toxicity of— | | Comparative toxicity of drug: Cocaine HCl = 1. |
|---|---|---|---|---|---|---|---|---|---|
| | | Drug. | Solution. | | | | Drug kilo/gm. | Alkaloid kilo/gm. | |
| | % | % | % | | | | | | |
| Cocaine . | 0·5 | 89 3 | 0·45 | 0·057 | 0 060 | 6 0 | 16·7 | 18·4 | 1·0 |
| Novoc. . | 3·0 | 86·6 | 2 60 | 0·38 | 0·40 | 6·7 | 2·5 | 2·9 | 0·15 |
| Borocaine E | 5 0 | 52·9 | 2·55 | 0·62 | 0 65 | 6·5 | 1·5 | 2·9 | 0·09 |
| Eth. bor. | 5·0 | 52·9 | 2·55 | 0·62 | 0·65 | | | | |

Cocaine = Cocaine hydrochloride, B.P. Novoc. = novocaine, Ethocaine hydrochloride (kerocain). Borocaine E = Ethocaine borate, B.D.H. Eth. bor. = Ethocaine borate, E. W.-W.

### *Anæsthetic Efficiency.*

If it is important closely to imitate the conditions of clinical usage when estimating toxicity—though such an estimate will only give us an approximate guide in practice—it is still more important when appraising anæsthetic efficiency, for the latter is the clinically essential matter. For the general user, "anæsthetic efficiency" implies a measure of the power of producing anæsthesia. If a given solution produces anæsthesia readily—that is, rapidly—we say *that its anæsthetic efficiency is high,* and vice versa. There being no absolute standard, all our estimates are comparative. If two solutions produce anæsthesia in the same time we can say that their efficiency is the same, and thence deduce the relative efficiencies of their constituents.

The phrase "surface anæsthesia" implies anæsthesia resulting from surface application; it must not be confounded with "superficial anæsthesia." At least in the nose, the latter is relatively unimportant, though readily produced. It is for operations involving cutting of bone, &c., that real anæsthesia is necessary. The phrase, therefore, should mean *good anæsthesia down to and including the periosteum.* Such a standard of comparison brings out the real value of different drugs; those that penetrate the tissues slowly produce this deep anæsthesia with difficulty—their "anæsthetic efficiency" is low.

### *Animal Experiments.*

As Le Brocq pointed out in 1909, animal experiments on surface anæsthesia are apt to be very unsatisfactory. The animal does not uniformly indicate pain. We do not know, for example, that the stimulus provoking a leg reflex in a frog bears any but the most superficial resemblance to what man calls pain. And if we rely on the corneal reflex in a mammal, we are probably measuring abolition of sensibility to touch rather than to pain. At least, in man it is easy to show that the reflex is abolished before the cornea is surgically anæsthetic.

There is another, and more serious, objection to the cornea. It is a structure unique in (*a*) thinness of covering epithelium, (*b*) type and distribution of nerve-endings and fibrils, (*c*) vascular arrangements, and (*d*) is devoid of mucous glands, &c. Whatever it may be, it does not at all resemble mucous membrane. Nor can we expect results obtained for the one tissue to apply to the other.

But the efficiency of drugs of this class can be readily ascertained by direct observations in man, under the actual conditions of practice. There is no need for any extensive investigation under the difficulties inseparable from animal experiment.

*Method.*—What is necessary is to find out under what conditions a given drug produces good anæsthesia. It is "begging the question," for example, to make applications under predetermined conditions as to time or concentration. The time sufficient for one solution may be inadequate for a second, and more than enough for a third. Yet under proper conditions all will give complete anæsthesia; failure to produce the latter, at least with any preparation commercially available, is a reflection on the technique, not on the drug. All that is shown by a "fixed time" experiment is whether or no the technique is suitable for the drug in question.

Several investigators have measured the *duration* of anæsthesia, and assumed that this is a function of anæsthetic efficiency. The two may be related, but the connexion is obscure. In fact, one may be varied without altering the other. But, at least in nasal surgery, it is rarely that difficulty arises from short duration of anæsthesia once this has been effected.

### *Efficiency of Borocaine E.*

The method evolved by the author is, briefly, as follows. The minimum time is measured from the completion of packing the nose to the onset of complete anæsthesia of bone. In a series of experiments the average time for this to occur with a given solution is determined. The concentration of cocaine hydrochloride, B.P., that will act in the same time is also found, and the comparative efficiency of the two drugs calculated. Good anæsthesia implies that neither flinching nor lacrymation occurs. With borocaine E 5 per cent. solution the best result in six operations was "fair" twice, the rest being "poor," even when packing was continued for 12 minutes, with three changes. A 20 per cent. solution was therefore made, both with the author's preparation and the commercial, and after one or two failures good anæsthesia was produced in 12 successive operations; the average time for this was 9 minutes 46 seconds, or 586 seconds. The method of comparison is shown in Table II. The values found for novocaine are included for interest, as the author had reported (by request) on this drug early in 1925.

TABLE II.

| Drug. | Concentration per cent. of— | | Time taken to produce complete deep anæsthesia in seconds. | Concentration of cocaine HCl producing anæsthesia in same time. | Comparative efficiency of— | |
|---|---|---|---|---|---|---|
| | Drug. | Alkaloid. | | | Drug, cocaine HCl = 1. | Ethocaine, cocaine = 1. |
| Cocaine HCl, B.P. | 2·0 | 1·8 | 483 | — | 1·0 | 1·0 |
| Novocaine, ethocaine HCl .. | 20 | 17·3 | 411 | 2·2 | 0·11 | 0·11 |
| Borocaine E, ethocaine borate .. | 20 | 10·0 | 586 | 1·8* | 0·09 | 0·15 |

* Calculated.

Since we desire a high efficiency combined with a low toxicity, a convenient measure of value of one of these drugs is obtained by dividing the figure obtained for the former by that obtained for the latter. It is usual to take the value found for cocaine hydrochloride as unity in each case. This has been done in Table III. From this table we see that ethocaine, whether as hydrochloride or as borate, has a value about the same as that of cocaine hydrochloride, as tested by power of producing deep anæsthesia in the nose, but that the borate is about one-third more useful than the hydrochloride. It is suggested, however, that the variations from unity obtained in this manner are within the limits of experimental error. That, in fact, the power of any drug of paralysing the nerve-fibrils beneath the surface is proportional to its power of paralysing the nerve tissue of the medulla. In other words, anæsthetic efficiency is proportional to toxicity. But this is a digression.

TABLE III.

| Drug. | Comparative toxicity: Cocaine HCl = 1. Table I. | Comparative efficiency: Cocaine HCl = 1. Table II. | Cocaine efficiency ratio. |
|---|---|---|---|
| Novocaine .. | 0·15 | 0·11 | 0·7 |
| Borocaine E .. | 0·09 | 0·09 | 1·0 |

### *Other Properties of Borocaine E.*

Borocaine, like cocaine hydrochloride, can be boiled for a short time without damage; prolonged boiling causes decomposition. A 2 per cent. solution was prepared in the same manner as cocaine solution and left in its stoppered bottle; at the end of four days it had begun to turn brown, and was quite a definite brown colour by the end of ten. The properties, physical and therapeutic, of this solution were not the same as those of fresh solution, and it appears definite that some decomposition had occurred. The stability in aqueous solution, therefore, seems poor.

All the timed observations reported above were made after the addition of adrenalin 1/10,000. With this, though shrinkage was good, the mucosa was often not well blanched; it is suggested that perhaps the adrenalin had penetrated more rapidly, and so acted on tissues not reached by the borocaine. The onlookers remarked the redness of the mucosa and the definite tendency to bleeding. In five cases, after operation, the nose "fairly poured" mucus tinged with blood. A trivial smarting was observed on application of the 20 per cent. solutions; no case of late irritation was seen, nor was any evidence of toxicity observed. In three cases 5 per cent. borocaine without adrenalin caused definite congestion in the nose. This drug does not appear likely to be very useful for nasal work. It is only fair to state that the proprietors, though claiming "borocaine entirely supersedes cocaine," recommend it for the eye, throat, and urethra, but make no claim that it is suitable for nasal work.

### *Summary.*

1. Experimental methods of estimating toxicity and efficiency are considered. 2. The experimental toxicity of three drugs is shown to be in the proportion: cocaine hydrochloride, 1; novocaine, 0·15; borocaine E, 0·09. 3. The efficiency of the same drugs, as measured by the production of deep anæsthesia in the nose, after application to mucous surface, is found to be in the proportion: cocaine hydrochloride, 1; novocaine, 0·11; borocaine, 0·09. 4. Certain other properties of borocaine are discussed.

---

# A LUNG SPLINT.

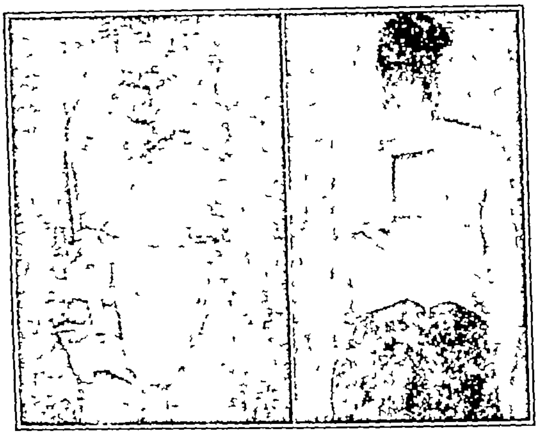
BY R. C. WINGFIELD, M.B., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, BROMPTON HOSPITAL SANATORIUM, FRIMLEY.

LIMITATION of movement of diseased portions of the lung has long been recognised as a very important factor in the treatment of pulmonary tuberculosis. It is the principle that underlies the artificial pneumothorax and the various thoracoplastic treatments that are in use at the present day. Before the development of collapse therapy, and even since, in order to avoid drastic procedure perhaps of doubtful value to the patient, attempts have been made to secure this limitation of movement by mechanical means, such as the use of heavy sandbags on recumbent patients, various plaster-of-Paris and other splints, or prolonged posturing, &c. None of these have been very successful for various reasons.

In the majority of cases it is the upper halves of the lungs that are the more grossly diseased, and it is the control of the movement of this region that presents a difficult problem. I have felt for a long time that in cases of unilateral or bilateral disease, where the lesions were massed towards the ap
that if the movement of the diseased parts of

could be limited by even so little as 1 cm. during each respiration the chance of healing and fibrosis would be tremendously increased. In such cases where collapse therapy was impossible or inadvisable I have attempted to control the movement of the upper half of the thorax by what I called an "apex belt," a webbing band 3 or 4 inches broad strapped as tightly as the patient could stand it, encircling the chest as high as possible under the arms. The choice of case was limited, but the results were encouraging.

FIG. 1.

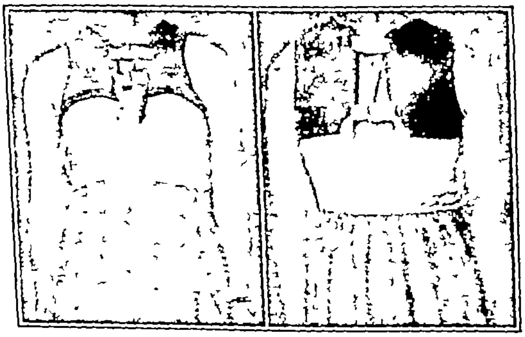


Single open splint showing attachments.

The apex belt, however, had many disadvantages. It was uncomfortable, it was bilateral in action, and it did not control the true apical movement. After some experiments I have devised the splint shown in the accompanying illustrations. It does control apical movement, is entirely unilateral in its action, it does not interfere with manual work, and, if properly made, is not unsightly.

It consists of an aluminium shoulder-piece, covered with rubber and lined by a rubber pneumatic bag which can be inflated to any desired pressure. It exerts an inward pressure in all directions, the power being derived from its own rigidity and by anchoring it to the opposite shoulder and thigh, as can be seen in the illustrations, and in this manner it does not interfere in any way with the movements of the opposite lung. The splint and accessories weigh about 1 to 1¼ lb.

FIG. 2.



Bilateral open splint. Back view.

The early results of its use are apparently encouraging, but, like all other adjuvants to the treatment of pulmonary tuberculosis, its exact value in individual case is incapable of proof. It is in the that its principles and construction may so appeal to my colleagues in tuberculosis work that they will make a trial of it that I am emboldened to publish this description; for by this means alone can its true value, if any, be assessed.

One essential point is the accurate construction and fitting of the aluminium shoulder-piece. (My thanks are due to Mr. W. Nettleton, third engineer of this sanatorium, who has undertaken this, and who has evolved a very excellent technique for the construction of these splints. The rubbering, pneumatic fittings, and strap attachments have been ably carried out by Messrs. Allen and Hanburys, Ltd., who are prepared to make the splint entirely.) Another essential is the fitting of the deflated splint in its right position, by careful adjustment of the tension of the various straps to suit each individual chest, before it is blown up.

The splint is naturally uncomfortable at first. But if it is carefully adjusted, and if only a slight pneumatic pressure is used for the first few days and gradually increased, patients will wear it without any discomfort during the whole 24 hours.

# Clinical and Laboratory Notes.

## TWO CASES OF HÆMOLYTIC ICTERUS TREATED BY EXTIRPATION OF THE SPLEEN.

BY L. S. HANNEMA, M.D.,
CHIEF PHYSICIAN TO THE MUNICIPAL HOSPITAL, ROTTERDAM.

THE two cases here recorded presented similar features and were both treated by splenectomy, with favourable results which have lasted for three years and 18 months respectively.

CASE 1.—An unmarried woman, aged 37 years, had had a large spleen from her childhood, with, as long as she remembered, a light yellow discoloration of the scleræ. Her father had always been somewhat icteric and several of her relations had a yellowish complexion. From her sixteenth year she had suffered occasionally from pain in the left side, during which attacks the icterus was more pronounced. As a rule the urine was dark and the fæces of normal colour. For the last three months she had been getting weaker and suffered from anæmic complaints, although previously she felt quite well. On examination she had a slight icterus. The mucous membranes were anæmic. Pulse normal. No glandular swelling. No anomalies of heart or lungs. The liver was slightly hypertrophied, its surface was smooth. The spleen was very large and consistent and extended nearly to the iliac crest and the median line. The urine contained very much urobilin, no bilirubin. The stools were of normal colour. Examination of the blood made out that the hæmoglobin content was 55; erythrocytes 2,600,000, leucocytes 10,500 (8700 were polymorphonuclear), thrombocytes 500,000 (!). There was a marked polychromatophilia and many normoblasts, indicative of the activity of the bone-marrow. The erythrocytes showed fragility, and with 0·6 per cent. NaCl a large number had been hæmolysed. Complete hæmolysis was attained only with 0·2 per cent. (which probably proves a marked bone-marrow reaction).

We had therefore to do with an icteric and strikingly anæmic patient. It is well known that an increased hæmolysis generates a considerable quantity of bilirubin, by which iron is set free, for the greater part in the liver. This excessive formation of bilirubin which is discharged into the intestines results in an increased excretion of urobilin per rectum (normally ca. 150 mg. in 24 hours). An excess of urobilin is absorbed, the liver cannot retain all of it, and so urobilinuria appears. A third symptom of exaggerated hæmolysis is a rise of the bilirubin content of the blood-plasma which may induce icterus, for jaundice may originate from an increased hæmolysis, as well as from bile retention. Hymans van den Bergh[1] has pointed out that by means of a *serum reaction (the so-called direct diazo-reaction)* retention icterus can be distinguished from hæmolytic icterus. In my patient this diazo-reaction was negative (as is always the case in hæmolytic icterus), quantitatively the bilirubin content appeared to have very much increased (determined after Hymans van den Bergh's method,[1] 1 : 50,000; normally ca. 1 : 800,000). An intense urobilinuria was recognised; the amount of urobilin of the fæces has not been determined for this patient. Consequently, an *intense hæmolysis was manifest.* From what has been said it is clear that we were justified in diagnosing the case as one of hæmolytic icterus, that is to say, the hereditary form. Apparently the bone-marrow had been competent to compensate the increased hæmolysis, but for some months the increased hæmolysis had got the better of the still active bone-*marrow, and the patient became anæmic.*

---

[1] Der Gallenfarbstoff im Blute.

Before discussing the question of treatment I will describe a second similar case.

*CASE 2.—A man, aged 20, complained of intense lassitude, from which he had been suffering for four months.* For several years he had been slightly jaundiced. He had noticed nothing abnormal about his stools and urine. No pruritus, no pain. He is of a healthy family, with no history of icterus. On examination he presented the brownish-yellow colour, characteristic of hæmolytic icterus. Scleræ yellow. Mucous membranes anæmic. Pulse normal. No glandular swelling. Heart and lungs normal. Liver somewhat enlarged, normally smooth. Spleen very large and consistent, extending to the median line. In the urine an excess of urobilin, no bilirubin. Examination of the blood revealed that the hæmoglobin content was 40; erythrocytes 2,280,000, leucocytes 10,000 (7000 polymorphonuclear). There was polychromatophilia, a good *many normoblasts,* a great many cells with Jolly Howell's corpuscles. With vital staining 50 per cent. of the erythrocytes exhibited the so-called vital granulation of Fiessinger. The patient's serum was bright yellow, and had a bilirubin content of 1 : 30,000. The direct diazo-reaction of Hymans van den Bergh was negative. The amount of urobilin secreted in 24 hours per rectum was 3 g (normal ca. 150 mg.). All the symptoms pointing to excessive hæmolysis were therefore present. The resistance of the erythrocytes to hypotonic salt solutions appeared to be considerably reduced; already with 0·7 per cent. NaCl hæmolysis took place.

### *Discussion.*

All went to show that here also we had to do with a hæmolytic icterus, whether acquired or inherited could not be decided from the anamnesis. The clinical aspect favours the latter view. Furthermore, it appears from the blood picture that the bone-marrow was highly active in combating the anæmia generated by the increased hæmolysis; the anamnesis shows us that in the past this action had been successful, but in the last few months the bone-marrow apparently failed in its task. In both patients the question arose what had to be done: Would *extirpation of the spleen* be the proper treatment?

When Chauffard published his first observations on hæmolytic icterus he believed it to be a harmless disease that entailed hardly any suffering, and did not require any therapeutic measures: "Ils sont plus ictériques *que malades.*" *In fact,* most of the cases are harmless, and slightly icteric patients with an increased hæmolysis, which is entirely compensated by the bone-marrow, can live their lives in *pretty* good health, without complaints worth mentioning. However, there are cases like those mentioned, in which the destruction of the blood is such as to put too great a strain upon the bone-marrow, be the latter ever so active.

Extirpation of the spleen may result in a considerable abatement or the total disappearance of hæmolytic symptoms. Indeed, for Addison's anæmia (the so-called pernicious anæmia) extirpation of the spleen has often been recommended as the proper therapy. In this affection, however, anticipations have been falsified, as the patient soon relapses into his former condition. Records of extirpation of the spleen in hæmolytic icterus are still few. There are cases, however, that lead us to expect better results than in pernicious anæmia. In either case hyperplasia *of the bone-marrow exists; in hæmolytic icterus it* should seem that this is the only change of the bone-marrow, so that we have good reason to expect that the bone-marrow may be completely restored, when the increased hæmolysis is abolished.

### *Treatment by Splenectomy.*

As we feared a fatal issue in our cases without intervention, extirpation of the spleen was decided on.

The first patient was operated upon in July, 1922. The *removal of the enlarged spleen was easily accomplished.* Under the microscope it exhibited all the features familiar to us in conditions of increased hæmolysis (everywhere numerous erythrocytes outside the vessels, phagocytosis of erythrocytes, high endothelia of the sinuses of the venæ). The patient recovered well from the operation and soon after regained her health. The icterus and anæmia disappeared. Six months after the operation the hæmoglobin content appeared to amount to 75, erythrocytes 4,800,000, leucocytes 12,600, thrombocytes 800,000. The blood preparation no longer contained normoblasts, nor was any polychromatophilia distinguishable; there were, however, a few cells with Jolly Howell's bodies. The indications of increased hæmolysis had disappeared; in the urine only a trace of urobilin was demonstrable; the bilirubin content of the serum was now 1 : 250,000, which is practically normal.

When determining the resistance of the erythrocytes to hypotonic salt solutions, I was struck by the fact that it *had not been modified by the operation. Three years after* operation patient was again examined. She still enjoys perfect good health. On examination the blood was quite normal; the resistance to hypotonic salt solutions, however, *was the same as prior to the operation.*

The second patient was operated upon in the beginning of 1924. The operation was uneventful. In the enlarged spleen we noted the same microscopic changes as in the first case. A month after the operation the hæmoglobin content was still 40, two months later 70, three months later from 80 to 85. Then the erythrocytes numbered 4,900,000. A slight leucocytosis of 10,000–15,000 still persisted. After two months there were no normoblasts, no polychromatophilia, a few cells showed Jolly-Howell's bodies, while the number of erythrocytes with so-called vital granulation had become normal (3 per cent.). After three months the marked urobilinuria had much improved, but urobilin was still demonstrable in the urine. The bilirubin content of the serum, which amounted to 1 : 30,000 ante-operationem, now appeared to be 1 : *200,000. There* was an excretion of almost 1 g. of urobilin per rectum every 24 hours (ante-operationem 3 g.). This pointed to considerable improvement, although the values obtained were not yet normal. Just as in the first patient, *the resistance of the erythrocytes to hypotonic salt solutions remained unaltered.*

*I saw the patient again lately.* He looked and felt quite well and there was *not* a vestige of icterus left.

### *Results of Operation.*

In both patients extirpation of the *spleen has* yielded the favourable results we had anticipated. It is interesting to discuss what the further prognosis will be. In my judgment the increased fragility of the erythrocytes should not be regarded in all cases in a similar way. In the literature cases are on record in which the symptoms cannot be due to the spleen, while in others the *extirpation of the* spleen caused the symptom to disappear altogether. May it be possible that the prognosis of the operated cases depends upon this? I mention from the literature a case of Banti, reported ten years after the extirpation of the spleen, in which the favourable condition had maintained itself; here the lowered resistance of the erythrocytes which existed before the operation had given place to normal values. It is not without the bounds of probabilities that we may learn from a wider experience that the persistence of the less resistant erythrocytes may lessen the chances of lasting benefit from the operation. It is notorious that in pernicious anæmia after splenectomy other organs can bring about the increased blood destruction. The danger is not imaginary that in the long run, perhaps after years, the less resistant erythrocytes, which continue after *splenectomy in cases of* hæmolytic icterus such as the above described, may in this disorder be the cause of a reappearance of the increased hæmolysis.

## A CASE OF
## EXCEPTIONAL HYPERGLYCÆMIA WITHOUT COMA.

BY E. BOSDIN LEECH, M.D. CAMB.,
HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY;
AND
GARFIELD THOMAS, M.SC. MANCH., A.I.C.,
SECOND ASSISTANT TO THE DIRECTOR OF THE CLINICAL LABORATORY AT THE INFIRMARY.

IT would seem of interest to put on record the following case of diabetes mellitus in which the patient was not comatose and yet had in his blood a concentration of more than 1 per cent. of reducing substances (estimated as glucose).

On Nov. 4th, 1924, H. E. T., a male, aged 27, attended the out-patients' department of this hospital complaining of excessive thirst, weakness (he had walked to the hospital, but was very faint on arrival), blurred vision, especially in the right eye, and frequency of micturition. He was quite rational and stated that he had felt weak for about three months and that at times he had been very unsteady on his feet. He added that the excessive thirst had been noticed only during the week just past, and that on account of the parched state of his mouth he had been feeding, during that time, on "bread and milk."

*Condition on Examination.*—The tongue was found to be very dry; the pupils of the eyes reacted to light and accommodation, and there was no diminution of visual field; acetone was not noticed in the breath. The urine had a specific gravity of 1030; it contained a large amount of sugar, a trace of acetone, no aceto-acetic acid, and no albumin. In attempting to estimate the blood-sugar by the MacLean method it was found that, when 10 c.cm. of the filtrate were used, the volume of N/400 thiosulphate required was less than 1 c.cm.

It was decided that the patient should be admitted at once, but, at his special request, he was allowed to return home before entering the ward as an in-patient. On his return a couple of hours later it was found that during this interval he had taken more "bread and milk." The blood test was repeated in duplicate (using only 5 c.cm. of the filtrate for the estimation of the sugar) and the concentration of sugar was found to be 1·2 per cent. In the ward drinks were given freely. During the first 24 hours insulin was not given; dieting was at the rate of 560 calories per diem (made up of carbohydrate 26·5 g., protein 54 g., and fat 26·5 g.). By 10 o'clock on the following morning the blood-sugar had fallen to 0·335 per cent.; the breath then smelled strongly of acetone, but the urine contained no aceto-acetic acid. At midday 10 units of insulin were given and the diet was increased to 1450 calories per diem (made up of carbohydrate 46 g., protein 52 g., fat 117 g.). On the following day 5 units of insulin were given, morning and evening, and the diet was not changed. This was continued for a week; the clinical data collected during that time are set out in the table.

| Date in Nov., 1924. | Diet in cals. | Total insulin per diem. | Pulse. | Blood-sugar % | Urine.* | | |
|---|---|---|---|---|---|---|---|
| | | | | | In oz. | Sp. gr. | Sugar. |
| | | units. | | | | | |
| 4th | 560 | 10 | 64 | 1·2 | 150 | 1030 | + + + |
| 5th | 1450 | 10 | 80 | 0·335 | 33 | 1038 | + + |
| 6th | 1450 | 10 | 80 | 0·188 | 38 | 1036 | + + |
| 7th | 1450 | 10 | 80 | 0·109 | 56 | 1032 | + + |
| 8th | 1450 | 10 | 84 | not est. | 76 | 1030 | + + + |
| 9th | 1450 | 10 | 88 | | 43 | 1036 | + + + |
| 10th | 1450 | 10 | 84 | 0·130 | 70 | 1036 | + + + |
| 11th | 1450 | 10 | — | 0·156 | — | — | — |

* Albumin nil. Aceto-acetic acid was absent until Nov. 9th. It was present (+ +) on the 10th.

The temperature varied between 97° and 98° F. It is unfortunate that the patient had to be discharged from hospital because he would not keep to the diet prescribed for him. He cannot now be traced.

---

LEEDS CAMPAIGN FOR SMOKE ABATEMENT.—At the request of the Health Committee the medical officer of health for Leeds has issued a circular letter urging on shopkeepers, occupiers of offices, and proprietors of large professional buildings the necessity of the entire abandonment of the use of raw coal and the adoption of smokeless methods of obtaining heat. It is stated that the change could be effected at a comparatively small cost, and the expense would be amply compensated by the results.

---

# Medical Societies.

## LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of this Institution held on Dec. 17th, 1925, Dr. WALLACE JONES contributed a note on the

### *Prognosis of Auricular Fibrillation,*

based on the analysis of statistics of a series of cases attending the Heart Department at the Royal Infirmary. The dominant factor in prognosis was the condition of the heart muscle. Information with regard to this would naturally group itself into (1) clinical evidence, (2) electrocardiographic findings. The symptoms accompanying the onset were very important and, when marked, indicated limitation of the reserve force of the heart and in consequence considerable myocardial damage. The investigation was made to determine the expectation of life from the time when the cases first presented themselves with symptoms of cardiac failure in the Heart Department until they died. It was shown that auricular fibrillation in these cases was more serious in senile than in rheumatic heart disease; that in mitral stenosis the expectation was slightly lengthened by the presence of auricular fibrillation, while in aortic regurgitation this effect was more marked. The prognosis was better in females than males in all types. In the electrocardiographic findings the presence of a bizarre Q.R.S. was of serious significance.

A joint contribution on

### *Sterility due to Impalpable Tubal Defects,*

by Prof. W. BLAIR BELL, Dr. R. E. ROBERTS, Mr. J. ST. G. WILSON, and Dr. S. B. HERD, was introduced by Dr. Herd, who outlined the accepted methods of treatment for sterility in the female, and showed how frequently useless vaginal operations might be performed. As a method for controlling surgical treatment, and avoiding unnecessary operations, the adoption of the tubal patency test by insufflation was held to be of great value. Reference was made to the work and methods of Rubin, Dickinson, Forsdike, and Blair Bell, and a description given of the technique and apparatus employed by the latter—a hand-bulb with reservoir manometer and cannula being used, and air the material employed. Thirty-one cases were tested in this way, and in none of these was there any serious discomfort or disability. Radiological examination was always employed, and in all cases operated upon the previous diagnosis as to the state of the tubes was confirmed. Insufflation was only used for diagnosis, and it was not claimed that the method had any therapeutic value.

Dr. R. E. ROBERTS gave an account, with illustrative skiagrams, of the radiological features in the diagnosis of

### *Patency of the Fallopian Tubes.*

The uterus having been insufflated, any air which has passed through the Fallopian tubes will tend to rise to the highest point in the peritoneal cavity, this point depending on the position of the patient. After the uterine insufflation the patient is therefore made to sit up or stand, and after a short interval in which the air has opportunity to rise in the peritoneal cavity an X ray examination is made of the diaphragmatic and hepatic area in the erect position, a skiagram being invariably taken. If the Fallopian tubes are both occluded no air will have entered the peritoneal cavity and the upper border of the liver cannot be differentiated from the diaphragm. If, however, one or other Fallopian is patent and air has entered the peritoneal cavity by this route, the air will have risen to the under surface of the diaphragm and will be shown in the skiagram as a translucent area between the diaphragm (which appears as a delicate curved line) and the liver, the extent of this translucent area depending on the amount of air which has passed in. Even very small quantities of air can, as a rule, be demonstrated by this method, but it is conceivable that if the tubes are almost occluded the amount of air entering the peritoneal cavity would be so small that it might become entangled in the mesenteric folds and so fail to reach the subdiaphragmatic area.

Mr. ST. G. WILSON was of opinion that inflation was most suitable for cases of "one child sterility" when several years had followed last confinement. Inflation alone cannot always be relied on for a correct result, and he therefore advised injection with lipiodol in all cases which gave negative results with inflation. The clinical signs of passage of air through the tubes were unsatisfactory; he therefore always recommended the help of the radiologist.

# Reviews and Notices of Books.

## TUBERCULOSIS OF THE HIP.

*The Diagnosis and Treatment of Tuberculosis of the Hip.* By G. R. GIRDLESTONE, B.M. Oxon., F.R.C.S., Hon. Surgeon, Wingfield Orthopædic Hospital, Oxford. London: Humphrey Milford, Oxford University Press. 1925. Pp. 94. 8s. 6d.

IN a small volume, well illustrated by skiagrams and agreeably written, Mr. Girdlestone describes the every-day work of a country orthopædic hospital in connexion with the diagnosis and treatment of tuberculous disease of the hip. The opening chapter, which deals with the preliminary diagnosis in the doctor's consulting-room or on his round, contains an exhortation that not only definite but atypical cases should be sent at once to an orthopædic clinic or out-patient department of a general hospital. No one with an extensive experience of this disease will dispute the wisdom of this advice, for a good functional end-result depends on the prompt application of constitutional and appropriate local treatment. The local treatment recommended varies according to the stage of the disease. For the first stage, that of activity, the Jones abduction frame is recommended and ambulatory methods are very properly condemned. Operation has no place in the treatment of children, but the author believes that adults, in whom sound fibrous or bony ankylosis is the goal, require arthrodesis whenever radiograms show definite lesions but not conditions favourable to ankylosis. In the second stage, which is defined as commencing three months after fever has ceased and satisfactory improvement has been shown by gain of weight and an appearance of returning health, it becomes necessary to decide whether to aim at a movable or a fixed hip. Mobility is aimed at when during a test period of weight and pulley extension the movement of the joint gets freer week by week. Ankylosis is the objective when radiograms or tests show that without ankylosis the limb is unlikely to become permanently safe and useful. It is easy, the author remarks, to fall between the two stools and end with either mobility that is not free enough in its range and firm enough at its limits to be safe, or with fixation that is not massive enough to be secure. He points out that weight-bearing joints are prone to osteo-arthritis, and of these the hip most seriously and most painfully; and that, whereas at every step the knee and ankle have to carry the weight of the body, the hip labours under such a mechanical disadvantage that it must bear twice that burden. If mobility is decided on as the aim of treatment, a weight and pulley extension is substituted for the fixed frame; if fixation, a plaster spica is applied which includes also the upper half of the thigh on the sound side. The third stage, defined as commencing three months after the beginning of the second stage, provided all signs of disease apart from sequelæ have disappeared, is treated, in the mobile group, by patten and crutches, then crutches alone, and finally sticks; in the fixation group, by plaster with patten and crutches, followed by plaster and crutches alone and eventually a modified single Thomas splint. In some cases it may take four or five years to achieve ankylosis. Sepsis is dealt with by drastic drainage operations and, if ankylosis is not occurring, excision of the upper end of the femur. The final section of the book is devoted to a critical consideration of end-results (we regret the absence of any statistics) and to a description of operations to correct malposition.

Altogether an admirable little book.

## A MANUAL OF HYGIENE.

By Sir WILLIAM H. HAMER, M.D., F.R.C.P., D.P.H., and C. W. HUTT, M.D., D.P.H. London: Methuen and Co., Ltd. 1925. Pp. 821. 30s.

HYGIENE is defined in the new Oxford English Dictionary as "a department of knowledge or practice which relates to the maintenance of health." An author who would deal compendiously with this department of knowledge must cover an impossibly wide field, relating to almost every human activity and treating as of first importance sociological problems not directly falling within the province of the art of medicine or the sciences on which that art is founded. Clearly some limit to the application of the word must be observed. It is surprising and not a little confusing to those who have to mould their teaching practice in conformity with the requirements of sundry teaching and examining bodies to observe the varying conceptions as to what hygiene means. We are relieved of any doubt in the case of this book, for the preface definitely states that its purpose is to meet the needs of those seeking to obtain a Public Health Diploma. It is from this limited aspect that its value must be assessed. The book is described as being based on Hamer's Manual of Hygiene (1902) and, though a good deal of new material is added, many passages are identical with those of the original manual.

The first four chapters deal in turn with Air, Water, Soil, and Food, and the fifth on familiar lines with the Collection, Removal, and Disposal of Refuse. Dr. Duncan Forbes has rewritten the chapter on Dwellings, Schools, and Hospitals, and (the late) Dr. James Niven contributes chapters on Tuberculosis, Sanitary Administration and Law. Mr. Kenneth Walker deals adequately with Venereal Diseases and Dr. Kenneth Fraser with School Hygiene. In other chapters the subjects of Infection and Immunity, Infectious Diseases, Disinfection, Vital Statistics, Maternity and Child Welfare are discussed in sufficient detail, but the book is kept within a reasonable compass. A certain lack of homogeneity is inevitable as the result of collaboration and of attempts to join new work to old, but the balance is maintained and little new work of real importance is omitted. The preventive idea underlies the whole volume, but for the benefit of students for the D.P.H. this might have been more definitely stressed and illustrated in each particular section. For instance, space given to irrelevant information on fire prevention, in the chapter on "Dwellings," might well have been devoted to the relation, if any, between housing defects and health. The real problems, too, in connexion with the disposal of domestic refuse—namely, the encouragement of fly- and rat-breeding—although they are mentioned, are not sufficiently distinguished from the æsthetic and psychological questions invariably confused with them in the public mind.

We miss further any definite indication as to the value of coördination within one department of all the older and the new public health services. The extent to which specialisation within the public health service is necessary or desirable or dangerous is surely a question of first-rate importance to the prospective health officer. The chapters on Maternity and Child Welfare and School Hygiene, each good in themselves, contain little reference to the complementary service or to the importance of continuous supervision by the same officers of children from birth to the age of leaving school. It ought to be brought more vividly to the notice of the public health student that the linking up of these clinical departments with the public health service is justified mainly by the opportunity it affords of studying disease and ill-health in the mass, perhaps pointing the road to reform, outside the province of medicine. It seems to us that a coordinating chapter might have been added with advantage, either as introduction or conclusion to the manual, and dealing with these questions, as well as the history of the growth of the service and its probable development.

The chapters on Infection, Immunity, and Infectious Diseases are quite admirable. Here the bearing of scientific and clinical knowledge on the prevention of disease is dealt with in a masterly way. The section on Tuberculosis is also excellent, though unnecessary space is devoted to the detailed bacteriological findings of Royal Commissions. These and the preceding criticisms are made because the study of public health covers such a vast field. Hence writers should aim at cutting down to the minimum the enumeration of disconnected facts and keep ever before the flagging mind of the student the underlying preventive idea which gives these facts their significance. Having criticised, we may add that this manual is one of the most useful books of its kind that we have examined. It presents well and clearly the type of knowledge which the health officer should have at his disposal, and is singularly free from printers' errors. The figure on p. 230 is inverted and we have failed to trace the reference in the index to Farr on p. 733. The system by which the names of writers have been selected for mention in the index is not quite obvious. For instance, the name Brownlee appears several times in the text but not in the index; indeed, the epidemiological work of this writer is, perhaps, deserving of more attention than the book gives to it. A complete bibliography at the end of each chapter would be a real undertaking, but if this procedure had been adopted the references at the foot of pages and in the index might have been dispensed with.

---

### CRIPPLED CHILDREN.

*The Care and Cure of Crippled Children.* Scheme of the Central Committee for the Care of Cripples. By G. R. Girdlestone (Oxford). London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd.; Bristol: John Wright and Sons, Ltd. 1925. 6*d.*

Although it is not so stated on the title-page, we are informed by the Secretary of the Committee that this is a revised edition of Part I. of the booklet which appeared in 1924. Since that time progress has been made, so that a complete scheme, as described in this pamphlet, of central orthopædic hospital, country town or village clinics, and after-care has either been or is in course of being established in 20 out of the 40 English counties. Information is here given as to the efforts that are being made to cure cripples, prevent crippling, and look after the interests of patients after treatment is at an end. The steps necessary to establish a county or county-group scheme, as originally achieved in Shropshire by Miss Agnes Hunt, and in the group of Oxford–Bucks–Berks by Mr. Girdlestone and his associates, are clearly set forth, and ideal plans for a central open-air hospital and a village clinic are also furnished. This pamphlet cannot be too widely circulated, nor the work of the Central Committee for the care of cripples too well known. This society, the office of which is at Carnegie House, 117, Piccadilly, W. 1, is also concerned in obtaining industrial training for the cured cripple. In the area under the London County Council there is a number of special (cripple) schools for physically defective children, and organisations exist which undertake to secure training and employment suited to the needs of cripples after their discharge from such schools. Th[illegible] are similar schools in some of the large towns [illegible], but by no means in all, and the committee is endeavouring to secure the same advantages for provincial cripples as those available in London. At present a difficult problem is presented to any surgeon in a country town or district who, having treated the deformity of a patient, is asked by philanthropists or relatives to tell them what can be done to train him or her to earn a living. In such a case application to the Central Committee should be made and will receive sympathetic attention.

---

### HISTORIC SCIENTIFIC INSTRUMENTS.

*Historic Instruments for the Advancement of Science.* A Handbook to the Oxford Collections prepared for the opening of the Lewis Evans collection on May 5th, 1925. By R. T. Gunther. London: Humphrey Milford, Oxford University Press. 1925. Pp. 90. 2*s.* 6*d.*

Dr. R. T. Gunther, the author of this interesting little handbook, is well known as an earnest student of the history of early science in Oxford concerning which he has written three very charming volumes. Dr. Lewis Evans recently presented his magnificent collection of astrolabes, dials, and other scientific instruments to the University of Oxford, and this collection is housed in the Ashmolean Building, which has thus reverted to its original association with the study of science. The collection was opened on May 5th, 1925, and Dr. Gunther is its very able and enthusiastic curator. He begins his handbook with an account of Ashmole and the old Ashmolean Building. Then follows a guide to the Evans collection of astrolabes and portable dials. The astrolabe is an important instrument not only on account of its use in astronomy and navigation, but on account of the extreme beauty of workmanship which some of the specimens show, and also because it was the first scientific instrument to be described in English and that, too, by no less a person than Chaucer. His treatise is still the standard work on the subject, but without an astrolabe to which to refer it is somewhat difficult reading.

The Oxford collection also contains many fine examples of globes, surveying instruments, telescopes, mathematical instruments, and microscopes. Among the latter are a Marshall's microscope of 1693 and an exact replica of Hooke's microscope purchased at the Crisp sale in 1925. This was the instrument with which Hooke, for the first time in the history of mankind, saw cells. He cut sections of various vegetable tissues and noted the fact that the substances were made up of nothing but cells. Many other interesting instruments are included in the collection, notably the Orrery collection lent by Christ Church. Lord Orrery was a great nephew of Robert Boyle, and the collection contains two beautiful specimens of the astronomical instrument to which Orrery's name has been given. Dr. Gunther has a way of giving extraneous information which makes his handbook original; for instance, concerning theodolites he has a footnote: "The word theodolite is a favourite word with the composers of examination papers in which unusual derivations of words are asked. *Theodolite = theodelite*, a corruption of *athelida*, which was a corruption of *alhidada.*" The alidad, we may add, is the index which turns on a graduated circle and so shows how many degrees are cut off. A simple instance is the hand of a clock.

---

### OPERATING ROOM PROCEDURE.

For Nurses and Internes. By Henry C. Falk, M.D., Assistant Attending Surgeon to the French Hospital, New York; Instructor in Surgery at New York University and Bellevue Medical College. London: G. P. Putnam's Sons. 1925. Pp. 385. 15*s.*

In this little volume the author has endeavoured to supply a theatre sister with all the technical details she may require for her work. Commencing with a description of the operating theatre and its general equipment, he goes on to describe in detail the personal preparation of all those engaged in an operation and the various materials required. The arrangement of instruments and their care are described in some detail, and an excellent chapter deals with the important subject of how to keep theatre supplies. The preparation of a patient and the posture required for different operations are briefly but adequately described. The remaining half of the volume is occupied by a series of brief descriptions of the more common operations of surgery. The whole volume is elaborately illustrated by sketches which give a neat and clear idea of the instruments used and the method of their use. The book is the best we have seen dealing with this subject; it should be valuable to the nursing staff of a theatre, and there are few surgeons who would not learn or be reminded of something from its perusal.

### METABOLIC DISEASES.

*Die Stoffwechselkrankheiten in der Praxis.* By Prof. FRIEDRICH UMBER, Berlin. Munich: J. F. Lehmann. 1925. Pp. 163. G.M.8·60.

A SMALL work which seeks to bridge the gap between physiological research and its application in practice is always welcome. In Germany particularly, and to a lesser degree in this country, the war necessitated large-scale experiments in nutrition. It is true, as the author points out, that few entirely new conceptions emerged, but our previous knowledge was broadened and deepened. It is this extended knowledge that Prof. Umber presents to us. The thoroughness with which some of the subjects are treated may be gathered from the fact that some 90 pages are devoted to diabetes alone and to its treatment by insulin. This is, perhaps, symptomatic of a return to that interest in calories which for some time have been eclipsed by the more elusive if no less important accessory factors.

### PHYSICAL CHEMISTRY.

*A System of Physical Chemistry.* By WILLIAM C. McC. LEWIS, M.A., R.U.I., D.Sc. Liv., Brunner Professor of Physical Chemistry in the University of Liverpool. In three volumes. Vol. II.: Thermodynamics. Fourth edition. London: Longmans, Green and Co. 1925. Pp. 489. 15*s.*

THE importance of physical chemistry in medical and biological subjects has come more and more to the fore during recent years. In fact, medical students are now expected to be fully acquainted with the general principles of thermodynamics and their application to colloidal and allied phenomena. The necessary knowledge is usually sandwiched into text-books of physiology, whose authors tend either to assume a knowledge of the elementary principles of physical chemistry or else to enter into a wordy account of this subject not easy to follow. There are, of course, text-books of physical chemistry written especially for medical students. These are, for the most part, quite good, but they gloss over the really difficult sections, which are made much of in the bigger text-books of physiology. For example, Donnan's membrane equilibrium theory as applied to proteins and colloids occupies a very important place in physiology, yet these special books often ignore it altogether. The theory of the double electric layer also tends to be neglected, yet it is constantly spoken of by physiologists. Experience in teaching shows that whereas the medical student will follow the first law of thermodynamics, he has great difficulty in mastering the second. This is mainly due to the poor accounts in the books at his disposal.

The volume now under consideration deals with practically all those points required by the medical student. It opens with chapters on the first and second laws. These are admirably clear, and, in fact, contain just the amount of information required for biological purposes. Medical students would do well to read the first four chapters, even if they have to omit the mathematical section. The next chapters deal with deductions from the two laws—i.e., Le Chatelier's theorem, the phase rule, the Clausius equatracte. A good summary is given of Donnan's work and its application by Jacques Loeb to colloidal behaviour. This is certainly among the most concise and accurate summaries of these important views that we have read. The theory of the ionic micelle is dealt with in rather a brief manner, and perhaps the work of the late Sir William Bayliss upon this point might have received more emphasis. We deal here only with the points of biological importance. These are so clearly dealt with that the book can be recommended to anyone working upon physiological principles. A sound knowledge of mathematics is essential to a thorough understanding, but a great deal of valuable information can be obtained if the mathematical parts of the book are ignored.

*An Intermediate Text book of Physiological Chemistry with Experiments.* Third edition. By C. J. V. PETTIBONE, Ph.D., Associate Professor of Physiological Chemistry, Medical School, University of Minnesota, Minneapolis. London: Henry Kimpton. 1925. Pp. 404. 15*s.*

SINCE this work has reached its third edition it would appear to be a popular book in America, although it is little known over here. Prof. Pettibone's volume is an example of careful compilation, obviously the result of wide teaching experience. The ground covered is that customary to such books and no new features are added. The descriptions are all clear and accurate, but there are no distinctive points which make the volume of special value.

### JOHN STEARNE, M. AND J.U.D.

By T. PERCY C. KIRKPATRICK, M.D., Fellow and Registrar, Royal College of Physicians of Ireland. Dublin: University Press. 1925. Pp. 23.

THIS work is an address delivered by Dr. Kirkpatrick in the Royal College of Physicians of Ireland on the occasion of the 300th anniversary of the birth of John Stearne, founder of the College. Stearne was born on Nov. 26th, 1624, at Ardbraccan in the house of his grand-uncle, James Ussher, then Lord Bishop of Meath, who was translated in the following year to the Archbishopric of Armagh. Stearne entered at Trinity College, Dublin, in 1639, at which date the studies were arts, philosophy, and the superior faculty of theology. In 1641 occurred the Irish Rebellion, when the Provost of Trinity fled to England accompanied by some of his students, among whom was Stearne. Ussher, who, we regret to say, was then residing in England, gave Stearne an introduction to Samuel Ward, Master of Sidney Sussex College, and in 1642 Stearne matriculated as a pensioner and in 1646 graduated as Master. In 1643 Cambridge came under the heavy hand of the Parliamentary Commissioners and Ward was ejected and imprisoned. Stearne remained under Ward's successor, but in 1649 went to Oxford in the train of Seth Ward, a cousin of Samuel Ward, who was incorporated at Wadham College and made Savilian Professor of Astronomy. Stearne retired to Bedfordshire, and in 1651 we find him, by an Order in Council, made a probationary Fellow of Trinity College, Dublin. Next year he was made a regular Fellow and started medical practice in Dublin. Where he had obtained any medical training is not clear, but presumably it was at Cambridge. The founding of the College of Physicians was upon this wise. In 1604 the corporation of Dublin had put up a building on the site of the present Trinity-street as a Bridewell "for putting idle persons to work." Sundry difficulties between the builder and the corporation led to the building being handed over to Trinity College for a school house, or rather a hostel for students. More difficulties arose as to possession and other matters, and eventually Stearne obtained leave from the Fellows to use the hall as a College of Physicians, he to live there and to be responsible for the expenses of repairs and upkeep. This was in 1651, and in 1667 Stearne obtained a charter from the King naming himself President and associating 13 other doctors of medicine as Fellows. Two of these Fellows had most unusual names, the one Samuel Sciclamore, which we imagine to be a variant of the name Siclemore, and the other with the still more grotesque name of John Unmusique. Two years after the granting of the charter Stearne died, and with the end of his life ends Dr. Kirkpatrick's most interesting address.

---

FLOWER SCENT.

By F. A. HAMPTON, M.A., B.M., B.Ch. Oxon. London: Dulau and Co. 1925. Pp. 133. 6*s.*

THE particularly emotional effect of the sense of smell has long been recognised, and it is common to find that the recall of a smell will conjure up a scene or an episode in a more prompt and definite manner than any recollection of a sight or a sound. It is therefore a loss to exact scientific writing or psychological assertion that no one has yet been able to think out a categorical nomenclature of smells, so that odour can be written and spoken of in the same way that may be employed with regard to what is seen or heard. The effect of sounds can be estimated up to a point in respect of their loudness by arranging a scale of distances, and visual appreciation up to a point can be gauged in a similar way. True, the standards thus arrived at are only general, and when an actual impression has to be conveyed the personal equation counts for much, but none of the parties in any discussion know what they are talking about. When smell is concerned, however, an actual vocabulary fails us in ordinary life, there being no common acceptation of any classification under which smells can be arranged. The sense of smell has been the least cultivated of the senses, and it is just possible that, if the subject had received the same attention as hearing and sight, the classification of odours would have reached a higher scientific plane though it suffers from the absence of the mathematical analysis which can be employed in optics and acoustics.

Dr. Hampton, dealing with the odour of flowers and their leaves, and taking into consideration its purpose and relation to man, has gathered together many interesting theories and facts with reference to the various scents of plants and presents them in a simple and coherent way. Pointing out that the scent of flowers and of most leaves is usually due to odorous volatile matter, he preludes his classification by chapters on the chemical composition of the active substances which produce scents, and their development and distribution as such. He quotes Count Kerner von Marilaun's classification made over 20 years ago, and points out the directions in which this is unsatisfactory, later chemistry having proved it to be partially unsound; and he proposes a modified classification, which he calls tentative and rough, but which will prove very interesting not only to lovers of flowers but to medical men. For many of us must at different times have been embarrassed in the attempt to find an adjective which suits an odour. The book, though small, is the result of wide reading to which references are given throughout at the close of each chapter.

---

NEW VERSE.

By ROBERT BRIDGES. Clarendon Press. 1925. Pp. 88. 6*s.*

THIS is a slender volume by the Poet Laureate, who is also a physician, as we are all proud to remember. It is composed of verse written in 1921 including a few earlier pieces, and a short preface explains the arrangement according to which the author has grouped what he calls "the distracting variety of this booklet." The poems in the first section are in Neo-Miltonic Syllabics, and the section is intended to make appeal to the advocates of free verse so that rigid scansionists must not expect to find it easy to make the right number of syllabic stresses. The second part is in Accentual Measures, concerning which controversy has now died down. Part III. presents no technical difficulties of metre to the ordinary reader, and for that reason will contain favourites for most of us; we can all understand from one poem or another how Dr. Bridges exercises his charm and to the close reader there will become apparent how far that charm depended on "the glow of a fire that burned steadfastly within." Part IV. consists of three short pieces, a translation from "Sappho," a pessimistic ode to Sir Thomas Barlow, and a vigorous denunciation, inspired by Catullus, of

"a filthy skunk amongst us,
A rank musk-idiot, the filthiest skunk."

Our medical Poet Laureate is not afraid of speaking his mind, but we wish he had not been moved to bracket his two predecessors in official bardery, for identity of Christian name is the least possible form of common denominator.

# Reports and Analytical Records.

## BACTOL MORGENSTERN.

(E. H. SPICER AND CO., 72, WIGMORE-STREET, LONDON, W. 1.)

THIS is a thick white emulsion with a faintly sweet flavour, the bottle containing 12 oz. When analysed the emulsion was found to contain 52 per cent. of heavy petroleum, a very small quantity of agar, and probably a trace of saccharin. The remaining 47–48 per cent. was water.

*Bacillus acidophilus* is said to be present (over 250,000,000 per c.cm.); it grows freely in alkaline media, the end product being lactic acid. It is claimed to create in the intestines a hydrogen-ion concentration which is antagonistic to the development of putrefactive bacteria. Whilst *B. bulgaricus* cannot establish itself in the intestinal tract and soon dies off, *B. acidophilus*, being a native of the bowel, rapidly re-establishes itself and multiplies freely in its normal habitat. Bactol presents the *B. acidophilus* in a stable form as it contains sufficient agar to maintain the viability of the bacilli and air is excluded by the petroleum. Bactol is thus superior to acidophilus milk and other cultures, which quickly spoil. It has the further advantage of obviating the necessity for the administration of large amounts of fluid preparations in order to attain "acidophilisation" of the intestinal tract.

## ANTIPHLOGISTINE.

(DENVER CHEMICAL MANUFACTURING CO., NEW YORK CITY, U.S.A.)

The tin of antiphlogistine examined contained 10·5 oz. of a slightly aromatic pasty mass with a faint brown colour, which is used as an external application for inflammation and congestion. It is claimed to be a perfectly harmless, non-irritating, non-toxic dressing with hygroscopic and indirectly anodyne properties. It is always ready for use, and maintains its properties under any climatic conditions. When analysed it was found to consist of 55 per cent. of inorganic matter of an argillaceous character. This was associated with glycerine, boric acid, and traces of iodine. The aromatic oils of peppermint, eucalyptus, and gaultheria are also said to be present. Antiphlogistine is a carefully prepared material, and is of undoubted use as an external application in a great variety of inflammatory conditions. Owing to the glycerine present, it keeps the tissues in a moist condition, and its antiseptic properties enhance greatly its general usefulness.

has been divided and the evidence has necessarily taken the form of a compromise, where the ayes and *the noes can agree with each other over many portions* of the dividing line. It has become clear that on the side of the Approved Societies nothing has been put forward justifying a clear demand for drastic procedure. The introduction of a wage-limit as a test for suitability to receive medical benefits is another great subject which has not been definitely settled. Before the war the difficulties of applying any practical income-limit *for manual workers* were *found insuperable*, and *from* the proceedings before the Commission it would seem hardly likely that the Insurance Acts can be revised immediately so as to apply an income-limit for manual workers, who constitute the vast majority of the insured population; while as far as dependants of the insured are concerned at the present time it is not, we believe, in the region of practical politics to attempt such a development. Wholesale admission of dependants is impossible, and we must remember where any partial treatment of the subject might lead. Here are two great questions which concern a substantial portion of the medical profession personally, and which deeply affect the ideals of all. They remain for settlement while many lesser matters have settled themselves. As a definite development in the whole Service allusion may be made to the culmination of a series of negotiations with the Ministry of Health under which there has now been drawn up a list of 600 practitioners throughout the country who are regarded as ophthalmic specialists, and who are willing to treat insured persons at a uniform fee of a guinea to cover each case of refraction. These points in the deliberations of the Royal Commission on National Health Insurance are singled out for mention as proving the comprehensive and also the detailed manner in which the inquiry is being held, and as showing that, while from time to time there may be no particular progress to be registered, vital changes of heart may be observed in the *mutual* attitude towards each other of the State on the one hand, and on the other of the beneficiaries and the executive under the National Insurance Acts. To appreciate this forms a gratifying result of stocktaking.

Looking along the developments of National Health Insurance, to see how far past experience and accomplishments indicate the more urgent work ahead, it becomes sufficiently clear that the *time has come* when the relation between medicine and the public should be better understood; for where clear explanations of medical ideals *can be framed* a great deal of public criticism will be obviated, to the immense benefit of the country. We have always considered *it* a fine testimonial to the influence of medicine that day by day the medical side of common affairs makes more frequent appearance in the public *comments* of the press and in the conversation of men and women. While it must be the policy before the medical profession to ensure *that* the conditions of medical practice should be such that the nation can obtain full scientific value from our efforts, the fact should be *openly* admitted that in many directions medicine is prepared to delegate technique, while retaining that general authority which is *conferred* upon practitioners by a course of arduous training guarded by stringent tests. During the close of last year the lay newspapers gave *evidence that*, while the public was prepared to acknowledge the development of medical science, it resented what it considered to be an *attempt* to reserve to qualified practitioners forms of treatment ancillary to medicine which could be rendered as well by the unqualified. Much of this criticism was misdirected owing to the complete misunderstanding, not only of medical ideals, but of the Acts of Parliament under which the profession of medicine is carried on. But, as we have said above, the medical profession has always had similar difficulties to surmount; it is a proof of its development that they should manifest themselves in various forms, and of its vitality that progress has been steadily maintained as the barriers of prejudice have been removed.

## THE OVARIAN HORMONE.

THE historical aspect of researches upon the ovarian hormone is of considerable interest; those who search carefully among the mass of material published on the subject will find that a great deal of accurate scientific work has been done. That the ovary is connected with secondary sexual characteristics has been known for hundreds of years, but it was not until the end of the last century that substitution therapy was attempted. **THEODORE LANDAU**[1] was the first to administer ovarian preparations by the mouth to patients who had been subjected to the operation of oöphorectomy. It is a striking fact that **LANDAU** never attempted to control his observations by animal experiments; in fact, 12 years of solely clinical research elapsed before **ADLER**[2] published an account of his animal experiments. In 1912 this observer stated that by injecting watery extracts of ovaries into animals he was able to produce all the symptoms of natural œstrus. From 1912 onwards a whole series of papers appeared on the subject, but it was obvious that the difficulties of standardisation were very great indeed. The methods used for this purpose consisted in injecting normal or spayed animals, and noticing the onset of signs of œstrus, such as enlargement of the genitalia, and symptoms of rut. The preparation of the active material had reached a very high pitch by 1915 **ISCOVESCO** (1912)[3] first suggested the use of alcohol as an extractant, and **FELLNER**,[4] **SEITY**, [5]**WINTZ**, and **FINGERHUT**[5] carried on this line of work. Undoubtedly the finest piece of research on these lines was that done by **HERRMANN** and **FRÄNKEL**[6] in 1915. These workers evolved a very sound method for the preparation of the product, and controlled their work by careful animal tests. The method consisted in a preliminary extraction of the ovaries with alcohol, and this solution was evaporated down. The solid residue was extracted with ether, and the phosphorus and nitrogen containing lipoids were precipitated from this solution by the addition of acetone. The final oily product was obtained by evaporating this solution to dryness. **HERRMANN** and **FRÄNKEL** studied the chemical and physiological properties of this substance very fully. Their brilliant researches lay dormant in the literature until 1923, when **ALLEN** and **DOISY**[7] fully confirmed the greater part of **HERRMANN** and **FRÄNKEL'S** claims. They were able to check their results much more accurately than **HERRMANN** and **FRÄNKEL**, since they adopted the method of **STOCKARD** and **PAPANICOLAOU**[8] for diagnosing the onset of œstrus. This consists in noting the alteration in the cell picture of vaginal smears during œstrus. **ALLEN** and **DOISY**, using a method almost identical with that of **HERRMANN** and **FRÄNKEL**, succeeded in producing artificial œstrus in their test animals. The former hold the view that the active principle is located solely in the Graafian follicles, and not in the stroma of the ovary.

**DICKENS**, **DODDS**, and **WRIGHT**[9] have repeated the work in this country, and have succeeded in confirming the observation that active material can always be obtained from fresh ovaries. The method of preparation used by them consists of slight modifications of those employed by **HERRMANN** and **FRANKEL**, and **ALLEN** and **DOISY**.

Pigs' ovaries were used as the main source of supply. The minced tissues were extracted with twice their weight of alcohol, care being taken not to lose any fluid during mincing. After stirring, the mixture was pressed out in a hand press through jean, and the solid material was then extracted in a Soxhlet apparatus with alcohol for 6–9 hours. The alcoholic extracts were then combined and filtered through Chardin papers. The filtrate was evaporated almost to dryness in vacuo, and the residue was taken up in a small volume of alcohol and filtered. On standing, a precipitate of fats and cholesterol separated which was removed by filtration. The solution was again taken down to dryness, and the residue was dissolved in a small quantity of ether, and twice its volume of acetone was added. The precipitated lipins were filtered off. The solid material was then redissolved in ether and again precipitated with acetone. This process was repeated several times. The filtrates were then combined and evaporated to dryness. The residue was dissolved in a small quantity of alcohol, and some cholesterol was removed by freezing. By repeating this process, it is said that the greater part of the cholesterol can be removed. The final product is obtained by distilling off the alcohol in vacuo.

Of a series of commercial preparations tested by **DICKENS**, **DODDS**, and **WRIGHT** all proved inactive. One specimen of whole ovaries, dried at 40° C, was found to yield 150 rat-units per kg. by the above method of extraction. The active principle consists of a clear, light brown oil, readily soluble in alcohol, ether, acetone, and olive oil. It can be heated to 200° C. without loss of activity. It withstands saponification only to a limited extent. The ovarian extracts made were standardised by the method used by **ALLEN** and **DOISY**—i.e., by determining the minimum amount which will bring about artificial œstrus in oöphorectomised adult animals as judged by **STOCKARD** and **PAPANICOLAOU'S** smear method. Rats were used almost exclusively. The extracts were injected subcutaneously, dissolved in olive oil or suspended in weak bicarbonate solution. If the extract was active, œstrus appeared sometimes after 24 hours and usually within 36 hours of the time of injection. The responsiveness of the animals was found to wear off with the lapse of time after oöphorectomy and larger doses became necessary for the production of œstrus. Thus 12 mg. of a liquor folliculi extract produced definite œstrus in a freshly spayed rat, while 50 mg. produced only slight pro-œstrus in a rat spayed three months previously. It must be remembered that three months correspond to 30 œstrous cycles in the rat, which is equivalent to two and a half years in the human female. After three months the genital organs of oöphorectomised rats are very thin and resemble fibrous cords. The effect of the preparation was also tested upon a female monkey; 100 mg. were injected subcutaneously, and within three days typical menstruation commenced. That this response was not the onset of a normal period was excluded by previous observations upon the animal. In a series of experiments in which the extract was administered by the mouth to oöphorectomised rats, œstrus could not be induced even when very large doses were given. By means of a series of injections an oöphorectomised rat was kept in a state of continuous œstrus for a period of 14 days. DICKENS, DODDS, and WRIGHT were unable to support the theory of ALLEN and DOISY that in the ovary it is only the liquor folliculi that contains the hormone. They also describe experiments to show that the active principle inhibits the blood-sugar lowering effect of insulin to a fair extent.

We have, therefore, two independent confirmations of the work of HERRMANN and FRÄNKEL, and it will be interesting to see how long it will take before active material appears on the market. Experiments of the observers already mentioned have conclusively shown that (*a*) fresh ovaries alone will yield active material, ordinary dried specimens being useless unless specially treated; and (*b*) the preparation is quite inactive when given by the mouth. In view of these findings, the inconclusive and contradictory results reported as to the therapeutic value of ovarian extracts given by the mouth are not surprising. Such success as has been recorded from oral administration of these extracts is presumably due to some other cause. The large-scale production of standardised active extracts will now be awaited by gynæcologists and physicians with eagerness.

## THE BRITISH SOCIAL HYGIENE COUNCIL.

THE year which has just closed has seen the National Council for Combating Venereal Diseases launching out on a broader programme of preventive education under a new name, thus bringing Great Britain into line with the Dominions, the Colonies, and the United States, where social hygiene councils already exist. When the National Council was established in 1914 there were certain reasons which led to the choice of the original name. The press as a whole never mentioned the words "venereal disease" and the public generally was ignorant of its heavy burden of preventable disease; nor were there more than the scantiest facilities for free treatment. It was necessary, therefore, to secure that infected persons should seek treatment and be able to obtain it easily. As far as publicity and the provision of treatment are concerned, the National Council has achieved its ends, and it is now considered desirable to attack the problem by widespread educative propaganda. This it is thought, no doubt with justice, will be more easily accomplished under the new title.

It would have been an encouraging start for the new campaign thus instituted if fusion between the National Council and the Society for the Prevention of Venereal Disease could have been brought about. A liaison committee of the two organisations, however, failed to agree upon the question of advertisements in chemists' shops, and the Society for the Prevention of Venereal Disease decided that fusion would be impracticable. However, alternative means of coöperation have been devised and a permanent liaison committee, consisting of five members of the executive committee of each organisation, has been established to take such joint action as occasion suggests. Further, Sir AUCKLAND GEDDES, who was already President of the Society for the Prevention of Venereal Disease and had been chairman of the liaison committee, has accepted the presidency of the British Social Hygiene Council. An example of the coöperation now existing between these two organisations is seen in certain negotiations which have been proceeding during the year between them, acting jointly, and the Ministry of Health on the question of the chemist's shop. These relate to the sale by properly qualified chemists of disinfectants and instructions for use approved by some competent authority. The liaison committee urged that this should be allowed, but that display of prophylactic packets should be forbidden and that the only advertising allowed should take the form of an approved notice in chemists' shops where disinfecting materials are on sale. The difficulty immediately arising from these proposals, as pointed out by the Ministry of Health, is the question of the "competent authority" necessary for the satisfactory working of any such scheme. The Ministry itself will not act and the Medical Research Council will not undertake the work. The liaison committee had suggested that the Society of Medical Officers of Health should be approached, but this was also open to various objections, and it was agreed by all parties to be impracticable. The problem of the provision of a competent authority is therefore still to be solved, but it is a great step forward that the two organisations which have so long taken different views have been able to agree upon the recommendation of a single policy, and it is possible that the outcome of the negotiations will be a joint recommendation by these two bodies of persons to constitute the competent authority.

The work already accomplished by the National Council is summarised in its tenth annual report, just issued. It is gratifying to see that the number of new cases of syphilis presenting themselves annually for treatment has fallen since 1920 from 42,000 to 22,000. Since the number of attendances at the centres has actually increased, this probably does represent a real diminution in the number of fresh infections. On the medical side, therefore, the attack on venereal disease is progressing satisfactorily, but, as Sir AUCKLAND GEDDES said in his presidential address, "no mere medical attack on venereal disease will ever of itself achieve victory." The social and moral problems involved also call for solution. Many "health weeks" and other public health campaigns now make use of the Council's propaganda, and one important feature of the wider programme now adopted has been the appointment of a social hygiene committee, which includes prominent biologists, psychologists, and educationists to advise the Council on the preparation of a syllabus of lectures to cover the wider field. With the aims and objects now set out and the wide educative programme contemplated all workers in the field of preventive medicine will be in sympathy, and the fresh activities of the Council under its new title will be watched with interest.

---

WE regret to announce the death in London, on Dec. 28th last, of Dame Louisa Aldrich-Blake, senior surgeon to the Elizabeth Garrett Anderson Hospital, and since 1914 Dean of the London (Royal Free Hospital) School of Medicine. Miss Aldrich-Blake was a pioneer among women surgeons; she was the first woman to obtain the M.S. degree of the University of London and to hold the post of surgical registrar to the Royal Free Hospital. She was in her sixty-first year.

# Annotations.

"Ne quid nimis."

## ATMOSPHERIC POLLUTION.

THERE are now 48 stations in the British Isles at which the monthly deposit from the atmosphere is measured, and their records for the year 1924–25 may be found in the Eleventh Annual Report of the Advisory Committee to the Air Ministry on Atmospheric Pollution.[1] Compared with the average of the previous five years there is a slight improvement; for example, out of 33 stations for which full results are available, the total deposit was below the average in 21 and above it in 12, whilst the deposit of tar, which is a smoke product, was considerably reduced as compared with the average. Sulphates, one of the most injurious parts of the deposit, showed a slight reduction, and at 18 stations out of 30 there was less of them than usual. The largest amount of tarry matter was in Newcastle-on-Tyne, which also had the highest tar deposit for the five years' average. The figure given for annual solids falling on a London area corresponds to 461 English tons of material per square mile, and an interesting feature of the report is a discussion of the ætiology of the celebrated fog which is more or less affectionately called "the London particular." Experiments in London and the suburbs have shown that its development is due rather to the replacement of water particles by smoke than to the dirtying of the particles themselves. In the suburbs a dense fog contains a large amount of water and little smoke, but in London the water droplets are reduced considerably in number and are replaced by soot. This conclusion is important because it proves that London fogs are not (as is so often assumed) a natural visitation which it is beyond the power of man to prevent. The fact seems to be that in the absence of soot to take the place of water there would be less natural fog in London than in the surrounding country, since the air over the city is warmer than elsewhere, and therefore the water particles which cause ordinary fog tend to evaporate. One of the special features of the report is a chart of results obtained in London which brings out the effect of wind on the concentration of impurity and shows that the concentration is inversely proportional to the wind velocity. Wind velocities below two miles an hour in winter are often accompanied by dense smoke hazes. Several methods employed in measuring dust have recently been described in our columns,[2] and an account has been given of that devised by Dr. J. S. Owens. The report contains some interesting observations made by Dr. Owens with his instrument—the jet dust counter—at the mouth of the St. Lawrence River and in Southern Portugal. The air in both of these situations contained little but crystalline salt particles, which are hygroscopic and begin to form fog of liquid drops before the air becomes saturated.

## THE EVACUATION OF SICK BY AEROPLANE.

IN their campaigns in Syria and Morocco the French have had to develop the transport of sick and wounded by air, and have gained much experience of what is now almost an essential service wherever casualties have to be evacuated from beleaguered garrisons or from posts on bad roads, in sequestered valleys, or on the other side of high mountains. In Morocco, where there have been over 11,000 French casualties during the year of fighting, the conditions have demanded the fullest possible use of aircraft under war conditions; but the use of air transport for carrying sick is also necessary in a country like Iraq, which is held, so to speak, from the air. British experience is by no means inconsiderable, as is shown by a contribution by Wing-Commander H. A. Treadgold, R.A.F.M.S., to the November issue of the *Journal of the Royal Army Medical Corps*, in which the achievements of the two countries are reviewed. Invalids from Iraq, he states, are now evacuated from Baghdad to Cairo in two days by air instead of in three or four weeks by steamer. The ambulance travels with the air mail, so that help may be available in case of accident, but no mishap has yet occurred amongst the 3000 cases moved. In the spring of 1923 198 cases of diarrhœa and dysentery were transported over the Aghdir Mountains from Suleimania (in the vilayet of Mosul) to Kirkuk—a distance of 100 miles direct, but at least 150 miles by road. The roads were poor, and on ponies the journey would have lasted a week, but the single transit by air was over for each patient in two hours. The cases were carried in Vickers-Vernon troop-carriers, which can take about ten men, with two stretcher cases. This means of transport is uncomfortable but swift, and the machines are available from ordinary troop-carrier squadrons. In addition to these, two other types of machine are available. In an emergency single cases can be carried quite comfortably by two-seater aeroplanes in Neil Robertson stretchers; they are wrapped up in special warm coats and strapped to the gun-ring and the outside of the fuselage. And there are now coming into use special ambulance aeroplanes (with larger engine-power, larger cabin, wireless, oxygen, body-warmers, and a w.c., with tank for dejecta), each of which will take two lying and four sitting cases. These will be drawn from special ambulance squadrons to be formed. To facilitate the evacuation of casualties the French troops make suitable landing-places immediately they occupy a new post, and this is very important. The best pilots are wanted for the service, but it is unpopular with them; they would rather be fighting. In order to combat this feeling the French Higher Command have put photographers, bombers, and pilots of medical aeroplanes on an equal footing for rewards. Good liaison is another essential factor. Pilots choose, in relation to weather and trip, a particular time for starting, and they cannot understand the unavoidable delays of medical officers, who in their turn fail to appreciate the reasons for the starting-time being so definitely named. This state of affairs seems to call for an Air Force embarkation medical officer and a small hospital close to the landing ground to receive and hold cases for embarkation.

## EMBRYOLOGICAL MATERIAL.

THE importance of embryology and of the study of intra-uterine changes, both in the fœtus and in its surroundings, and the bearing of these details of development on problems of pathological interest, are matters that are being gradually realised within the medical profession. What is not realised, perhaps, is the possible greatness of the importance. The ordinary courses in embryology which are prescribed for the student would be laughable in their inadequacy if it were not that they give him, at any rate, reason for knowing that the human body is not a preformed thing, fixed from the beginning, but must bear within itself certain inherited qualities and their stigmata, so that when he has to consider some pathological problem he may perchance remember that there are other questions behind those arising in the post-mortem room and pathological laboratory, and this may lead him to seek for authoritative information about them. It is here, unfortunately, that he is very likely to find himself at a loss. There are problems in development that have never been touched and others that have hardly been considered at all. Human organogeny has been worked out with fair accuracy and completeness in its broader aspects, but the finer points and the interplay of factors in the production of results, and the nature of the factors themselves, are still to be done, and it is here rather than in the larger matters that pathology will be looking for help. To give a simple example.

[2] THE LANCET, 1925, ii., 712.

of the differences referred to, the known stages of formation of the palate afford an explanation of the anatomical situation of the fissure, but not of the cause of a cleft palate. Here we want information on the factors which cause full growth of the maxillary process and on the causes of its failure in growth, and about these we know nothing. Such matters, more abstract and intricate, which do not come within the purview of the ordinary student, can only be slowly solved by those who devote their time to research of this sort, and they must depend for their material on the clinician, who alone is in the way of obtaining it. For this reason we should specially direct attention to the letter from Prof. J. P. Hill in our last issue. Embryologists can obtain specimens at all stages from most animals, but for human embryos they are forced to rely on the help of their practising colleagues. Much of the material procured in this way is abnormal, but that need not deter the practitioner from sending it, for the skilled study of abnormal formations may often throw light on dark places; it is of much more importance that its histological characters are fairly good, whence the attention to preservation asked for in the letter. The study of human embryology in England has hitherto depended on the use of private collections, and it is well to aim at the formation of a large and representative gathering of specimens, in which the help of the practitioner is essential, and surely will not be withheld.

## ENCEPHALOMYELITIS AND DISTEMPER.

RENEWED attention has of late been directed to lesions of the central nervous system in connexion with canine distemper. A meningo-encephalomyelitis was described in 1908 by Batten and Holmes in canine chorea—a recognised sequela of distemper—and subsequently a number of writers have confirmed and elaborated their description. Dexler had already drawn attention to changes in the brain less definitely associated with distemper. In 1923 and 1925 Kantorowicz and Lewy described the histological features of nervous distemper, and especially drew attention to the occurrence of groups of small bodies in the brain and cord, which they regarded as parasites and to which they attributed the morbid condition. These bodies are undoubtedly from their descriptions of the same nature as those which Craighead and Wright found in the brain of rabbits, and which have since been found in the brain and kidneys of rabbits and mice, and were called by Levaditi *Encephalitozoon cuniculi* and regarded by him as a form of microsporidium and the cause of an encephalitis. Manouelian and Viala found somewhat similar forms in the brain of man and animals dead of rabies, and believed them to represent the virus of that disease. The nature and pathological significance of these bodies is still under consideration. In the September number of the *Buffalo General Hospital Bulletin* Messrs. Benjamin Roman and Chauncey M. Lapp record the finding of inflammatory changes similar to those found by Batten and others in the central nervous system of 19 out of 29 cases of distemper (27 dogs, 1 cat, and 1 fox). In two or more of these 19 cases the clinical states were merely catarrhal, and nervous symptoms were absent. They suggest that a thorough search would reveal the typical lesions in the brain and cord in all cases of distemper. The changes which they described were very widely spread and patchy in distribution. They consisted chiefly of a lymphocytic effusion sheathing the small vessels and in some places surrounding the altered large motor nerve cells. The account given of the lesions in comparison with those of other forms of acute non-bacterial infective encephalomyelitis — e.g., encephalitis lethargica, herpetic encephalitis, poliomyelitis, Borna's disease and rabies—suggests that the histological changes in this group are very similar in kind, and are to be distinguished mainly by differences in their regional distribution and intensity. The last-mentioned authors regard the inflammatory changes as characteristic of distemper and probably constant in the different forms (catarrhal, intestinal, and nervous) of this disease. It may, however, be doubted whether, in the light of the recently discovered widely spread occurrence of similar lesions in several different kinds of animals, it is wise definitely to decide on the unity of a disease to which are attributed so great a variety of symptoms, until the experimental results of inoculating a purified or cultured distemper virus have been fully studied.

## WATER-SUPPLY AND CHLORINATION.

AT a recent meeting of the Public Works, Roads, and Transport Congress, Mr. I. G. Gibbon, Principal Assistant Secretary, Ministry of Health, recommended local sanitary authorities, at any rate the larger ones, to have a policy of water-supply in general outline for 50 years ahead, and a detailed programme for 20 years. In areas where neighbouring authorities had a common interest, either in the source or in the supply of water, he suggested the appointment of regional committees to ascertain the needs of all parties and how these needs could best be met, leaving the actual decisions to the constituent authorities. At the same congress Sir Alexander Houston regretted the tendency of large towns to fight for the possession of far distant gathering grounds for water impounding purposes, irrespective of the needs of their neighbours or of the country as a whole. A map of England and Wales showing the appropriated gathering grounds and the far distant towns supplied from them would, he said, make a startling picture and an alarming one from the point of view of those who have not made adequate provision for the years to come—"the unwise virgins of the water world." This rush for the uplands arose from the wise belief that it is better to drink a water which requires no purification than a water which has been purified by artificial means to a high standard of perfection. But the matter is really pressing, for although much can be done to prevent waste the consumption of water is continually increasing owing to the increased use of water for baths, lavatories, and washing operations in general. Sir Alexander Houston therefore contemplates the necessity soon arising of utilising for domestic purposes waters of doubtful origin, and he supports his view by considerations such as these:—

1. The interpretation of the results of the chemical and bacteriological examination of waters has radically changed within recent years.

2. Great progress has been made in the methods of rendering impure waters apparently safe to drink.

3. We have ceased to be obsessed by purely sentimental considerations.

4. Our administrators are more alive to the advances in science, and less inclined to be bound down by past traditions.

5. Over one-seventh of the population of England has been, and are, drinking with impunity, highly purified water derived from sources of questionable origin. This may be described as a physiological, or pathological, experiment on a vast scale.

6. If the absence of *B. coli* from a water is to be taken as implying the absence of the microbes of water-borne disease this organism can be practically eliminated by storage and filtration, and, if chlorination processes are super-added, absolutely destroyed.

7. There have been cases abroad where the addition of chlorine to impure water, which had previously been responsible annually for an enormous amount of disease and death, has resulted seemingly in the almost complete elimination of water-borne diseases.

If on this evidence the need for special purification processes is accepted, a little booklet just issued in a fourth edition entitled "Water Sterilisation by Gaseous Chlorine" will be found of considerable value. The Paterson Engineering Company which issues it has been responsible for large installations both in this country and abroad. Such questions as super-chlorination and de-chlorination, taste problems, chloramine sterilisation, disinfection of swimming-bath water, treatment of condenser cooling water, control tests of treatment, and the like are lucidly dealt with. The importance of duplication of essential machinery, a point too often overlooked, is strongly advocated. An emergency may readily arise in which a previously safe supply becomes suddenly polluted and unsafe. It is satisfactory to learn from the booklet that it is possible within 24 hours to have a chlorine apparatus installed and in working order. Solution of the chlorine in a minor body of water before addition to the main supply requiring treatment is the method advocated; this is much to be preferred to the addition of gaseous chlorine to the water through porous diffusers. Authorities contemplating chlorination, and their number increases daily, will benefit by the perusal of this little book.

## ARSENIC IN APPLES.

SEVERAL Hampstead tradesmen were recently prosecuted for selling Jonathan apples containing arsenic in quantity sufficient to cause complaint of illness after ingestion.[1] The Ministry of Health has now addressed a circular letter (No. 650) to authorities administering the Sale of Food and Drugs Acts, stating that the attention of the Minister has been drawn to the presence of considerable quantities of arsenic on the surface of certain imported apples. The circular continues:—

> Two cases of arsenical poisoning have been traced to the consumption of imported Jonathan apples, and a number of samples of these apples which have been examined have shown various amounts of arsenic ranging up to one-tenth of a grain per pound. The contamination of apples by arsenic has been occasionally reported for a number of years, but the quantities of arsenic found by analysis on former occasions have generally been insignificant, and until recently no cases of illness have been traced to the consumption of such apples. The amount of arsenic is liable to be especially large in apples grown in dry foreign climates where the apples are repeatedly sprayed during growth and the rainfall is not sufficient to wash off the deposit.

The Minister adds that importers of apples from the regions concerned are taking such steps as are possible to secure the removal of the contamination from future consignments, but he urges upon local authorities the necessity, especially during the next few weeks, of making full use of their powers under the Sale of Food and Drugs Acts, the Public Health Acts, and the Public Health (Imported Food) Regulations to protect the public by the examination of samples of apples likely to be affected and by arranging for the withdrawal from sale of apples which are found to be dangerously contaminated.

## SEXUAL OFFENCES AGAINST YOUNG PERSONS.

THE Departmental Committee appointed by the Home Secretary in July, 1924, to collect information as to the prevalence of sexual offences against young persons and to report upon any direction in which the law or its administration might be improved, has issued a report[2] which deserves close study. The Committee's 43 recommendations, which we print in another column, range over a wide area. Detailed discussion of them is impossible within brief compass, but we may at least draw attention to certain points of direct interest to the medical profession in Section 6 of the report (Matters Relating to the Offender), from which arise Recommendations 27 to 32. The Committee was pressed by not a few witnesses to advocate mental examination of all sexual offenders. There was, however, ample evidence of the great variety of the types of offenders, and, notwithstanding a common popular view to the contrary, there was no conclusive proof that most of such offenders are insane or mentally defective. The Committee took 200 examples of men certified in prisons as mentally deficient, and found that 50 of them were undergoing imprisonment for sexual offences. Conversely 108 examples were taken of men remanded to prison for indecent assault, incest, and carnal knowledge (the offences in all these cases being against young persons under 16), and none were found who could be certified as insane, while only 8 were certifiable as mentally defective. But there is one form of offence—namely, indecent exposure of the person—in which the proportion of mental instability is demonstrably high. Thus of 150 men remanded to prison for this particular offence 14 were found to be insane and 24 were certifiable as mentally deficient. Impressed by this comparatively large proportion, the Committee recommends that all persons convicted of indecent exposure should undergo mental examination. Further evidence failed to prove that sexual offences against the young are committed, as a rule, by habitual offenders, except in the case of indecent exposure, and except, to a lesser extent, in the case of indecent assault. In one large town, the report states, out of 77 men accused of sexual offences against persons under 16, only 5 had been previously convicted on similar charges. The Committee suggests that in this minority of cases of repeated offences, and also in any case where mental disease or defect is suspected, the offender's mental condition should be examined as already proposed in cases of indecent exposure. It recommends that the mental examination should be made by a mental expert upon a remand after conviction, and that the bench should act in accordance with the result of the examination. Only a few county or borough courts at present have the advantage of the services of a mental expert. It usually happens that the court has to rely upon the help of the local police surgeon or prison doctor who—although in most cases his assistance has been conspicuously valuable—has not always specialised in mental work so as to be an expert in mental disease. The Committee recommends that, when courts are not in a position to have the full-time services of a mental expert, arrangements should be made, without setting up new machinery or multiplying personnel, for the medical superintendent of the county or the borough mental hospital, or for the medical officer of the Mental Deficiency Act Committee, to serve as mental expert to the courts in the district. Another useful recommendation is one which THE LANCET supported some months ago,[3] when it was advocated in the report of the Prison Commissioners. It is that the Mental Deficiency Act should be amended by the elimination of the words "from birth or an early age." These words are an obstacle to proper certification. A case was mentioned in which a man had 50 convictions for indecent exposure, and was said by the local authorities to be a moral imbecile of hopeless character addicted to annoying school-children. Yet, because the doctors could not trace evidence of his mental history at an earlier age than 25, they could not certify him, although they knew him to be now and for many years past a proper subject for certification.

In general the Committee deprecates punishment of sexual offenders by way of fine; it considers probation sometimes suitable when fine is not; it declines to express an opinion on the time-worn but still vigorous controversy of whipping as a deterrent, and it concludes that imprisonment is the most suitable penalty in the majority of cases. It comments sharply upon the inadequacy of some sentences upon sexual offenders as contrasted with far heavier sentences awarded for offences against property. Where, as the result of mental examination by an expert, an offender is found to be insane or mentally defective, treatment will, of course, follow the usual lines. If there is no mental disorder, but there are repeated offences by the same person, the Committee recommends a policy of long periods of detention in special institutions. The problem of the elderly offender, whose acts are due to special physiological or psychological cause, is recognised. The Committee suggests that if the offence is an isolated one he can be placed on probation under supervision; if there are repeated offences, he should be confined in some non-penal institution.

[2] Report of the Departmental Committee on Sexual Offences against Young Persons. [Cmd. 2561.] London: H.M. Stationery Office. 2s.

[3] THE LANCET, 1925, i., 498.

Other points of professional interest in the report deserve mention. It is suggested that the services of women doctors be freely employed in the medical examination of young girls who are alleged to have been the victims of an offence. It is said that experience shows that where a girl has to be examined after complaint to the police there is less likelihood of causing her further mental disturbance if the examination is made by a woman doctor. As to the medical examination of an accused man the Committee moves cautiously. If the charge suggests the communication of venereal disease to the child, medical examination might enable an innocent man to clear himself; on the other hand, the medical examination may disclose evidence of disease which would corroborate the charge. The Committee rightly gives considerable attention to provisions for child welfare and to possible preventive measures, such as better housing, less overcrowding, more supervision in parks, cinemas, and school precincts, and the training of student teachers with a view to their giving sex instruction to the older children. Perhaps the most important, as well as the most controversial, recommendation is the proposal to raise the age of consent to 17, though on this point there is weightily reasoned dissent on the part of the legal members of the Committee—Mr. J. C. Priestley, K.C. (who replaced the late Sir Ryland Adkins as chairman); Mr. T. W. Fry, the metropolitan police-court magistrate, and Sir Guy Stephenson, Assistant Director of Public Prosecutions. On the whole the unanimity of the report is striking. It is not easy to reconcile conflicting opinions on vexed topics like these On the one side are the reformers, supported by a large and sympathetic body of voters throughout the country, and keenly sensible of the harm which sexual offences inflict upon the child victim. The reformers complain that there are too few prosecutions and too many acquittals; they want to give more jurisdiction to petty sessions, because juries at quarter sessions and assizes bring in so many verdicts of "Not Guilty"; they press for heavier punishments, a less rigid insistence on corroboration and strict legal proof, the abolition of all technical defences (such as that of "reasonable belief" that the girl was over the prohibited age), and a considerable raising of the age of consent. On the other side are the lawyers, and the judges recruited from the ranks of the lawyers, who insist that nothing must impair the traditions of law and procedure which are properly framed to ensure a fair and impartial trial. There is also what might be described as the Home Office view, sensible of the stronger arguments of both these parties and withal aware that it is undesirable to create innumerable fresh crimes, idle to enact severe punishments which courts will flinch from inflicting, and unsatisfactory to move too far in advance of a slowly instructed public opinion.

## THE HUMAN CONSTITUTION.

There has been for some years past an increasing tendency to direct attention towards what, for want of a more fitting term, is referred to as the human "constitution." The word has a familiar sound for the elders amongst us, and no doubt brings back to their minds memories of the great clinical physicians and surgeons whom they followed years ago. The acumen of these men, the way in which they would put an unerring finger on a patient's weak spots, seemed at times uncanny. Perhaps they would have found it hard sometimes to explain their grounds for an opinion, right though it proved to be, very much as we might find it almost impossible to say why we recognise with certainty someone whose face we cannot see, and whose garments are not those he wore when we last met him. Clinical instinct and insight retired modestly into the background when the laboratories and the researcher claimed the whole of medicine as their sole province; but it is again becoming evident that the human body cannot be explained in the laboratory or the dead-house. The subtle differences that make or mar an individual are none the less real because they are intangible, and herein lies the necessity for recognising the "constitution" of the individual. But this term has not quite the same meaning as it used to have; the modern conception is synthetic, it builds itself on measured data, and it cannot yet afford to stand away from a man and take a wide view of him. The fourth Henderson Trust Lecture,[1] delivered by Prof. W. W. Graves at the University of Edinburgh last October, is an admirable example of the material on which this new study of the individual man can be based. Prof Graves introduces us here to points about the scapula which will be new to many, if not to most, of us; he shows the hereditary nature of types, their persistence, and their indicatory significance with regard to morbidity and adaptability in general. As he has dealt with some 30,000 subjects, living and dead, his results may be considered fairly definite. Perusal of this interesting and important lecture makes one hope that in the not far distant future some use may be found for those portentous indices which sadden the reader of so many works on physical anthropology, and, if these can be made to show a value like that given to scapular types here, their accumulation, from the point of view of medicine, would be justifiable. The lecture should be read by clinicians; it cannot be much more than a rapid survey, within the limits of time of a lecture, but a full bibliographical index gives the reader the means to extend his acquaintance with the subject.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLIV.—THE TREATMENT OF CHRONIC MASTITIS.

The treatment of "chronic mastitis" has in the past been somewhat obscured by misunderstanding of its ætiology. It cannot be claimed that this is even now fully understood, but it is at any rate clear that the ætiology implied by the name which has so long been given to the condition is not the true one; consequently treatment aiming at allaying chronic mastitis on the supposition that it is an ordinary inflammation of the breast, due to a subacute infection with a pyogenic organism, such as a staphylococcus, is doomed to failure.

Sir Lenthal Cheatle has on many occasions stressed the necessity for a reform in the terminology of the chronic lesions to which the breast is subject, and has suggested the term "mazoplasia" instead of "chronic mastitis," on the ground that the epithelial changes so constantly found are the essential feature of the condition Epithelial changes are, however, only one incident in a pathological complex which it is almost impossible to summarise in a single word, and it may be wiser to postpone for the present any attempt to oust a term the use of which has become ingrained by the custom of so many years.

Chronic mastitis is not a disease of one age or sex, but is found in both sexes and, in its different forms, at all times of life. Its incidence is dependent, not on a bacterial infection, but rather on a disorderly process of secretion and absorption which are going on at all times in varying degree in a gland unprovided with an outlet except during lactation. The pathological and statistical evidence for these statements has been elaborated by me elsewhere.[1] In the present article no more reference will be made to ætiology than is necessary in order to indicate a rational basis for the treatment recommended.

---

[1] The Relation of Shoulder Blade Types to Problems of Mental and Physical Adaptability. By Prof. William Washington Graves, St Louis, Mo, U.S.A London and Edinburgh Oliver and Boyd 1925 Pp. 35 6d.

The mammary gland is provided with epithelium which is possessed of some secretory activity at all times of life. Its physiology is therefore intimately bound up with its pathology, and for present purposes its physiological history will provide some sort of arbitrary basis for indicating the lines upon which the pathological manifestations may be treated. The names used must be regarded as a matter of convenience rather than as representing the whole truth.

### *Infantile Mastitis.*

It may often be noticed that the breasts in a newborn child are enlarged and tender. It may even be possible to express from them a certain amount of secretion, and midwives have advised a systematic removal of this fluid. The activity of the breasts is probably due to the exposure of the infant before birth to the same hormonic stimulus which, in the maternal circulation, is tending to produce normal lactation. Interference with the breasts of the infant in this state results sometimes in infection, followed by an acute suppurative mastitis. If the breasts are left undisturbed, the congestion and enlargement will soon subside of its own accord. No treatment, therefore, is called for except, perhaps, the application of a sedative lotion, such as lotio plumbi cum opio, to allay any pain which the infant may be suffering.

### *Puberal Mastitis.*

Between the ages of infancy and the onset of sexual maturity the breasts are very unlikely to show any signs of activity, and attention will not be directed to them. It is common, however, for girls of about 12 years and for boys a year or two later to complain of a painful enlargement of the breasts for which their parents seek medical advice. Histological examination of breasts in this condition shows that the large collecting ducts are filled with a clear fluid secretion, but that there are no truly pathological changes in the epithelium or elsewhere. The pain is not severe, and can be endured. The patient and the parent can be reassured as to the harmlessness of the condition. In girls it will merge with the normal hypertrophy of sexual maturity; in boys it will persist for two or three years or even longer, and will eventually disappear. Seldom is any active treatment called for. Surgical treatment of the mammary gland in boys or young men will only be necessary in the rare cases in which the congestion of puberty has passed into the true hypertrophy called gynæcomastia. The gland can then be dissected out from beneath the nipple and areola, so that there need be no visible mutilation.

### *Menstrual Mastitis.*

From the onset of puberty in girls the activity of the mammary glands is closely associated with that of the ovaries, as indicated by the menstrual periods. In this connexion it is not uncommon to meet with women in the third decade of life in whom the usual clinical signs are absent or only slightly marked, but who complain notwithstanding of discomfort or pain in the breasts, this being greatly accentuated during, or just before, the menstrual periods. The treatment of such cases is usually difficult and unsatisfactory. Palliative treatment may be given, such as an application of glycerine and belladonna and the administration of potassium iodide. The breasts, if large, may be supported in the way recommended by Mr. Duncan Fitzwilliams, that is by the application of two vertical strips of adhesive strapping which start below the breast, pass over it on either side of the areola, and extend over the top of the shoulder. These measures may give some relief of pain, but usually it subsides only with the decline of the menstrual period. Sometimes the psychological condition of the patient is abnormal and the breasts receive a disproportionate amount of her attention, so that the treatment should be subjective rather than objective. If circumstances allow, marriage followed by pregnancy and lactation will prove to be the best solution of the difficulty. Operation should be avoided.

### *Chronic Mastitis.*

After the age of 30 the incidence of true "chronic mastitis" rises rapidly, and with it the proportion of cases in which the usual local signs of the disease become more obvious. At the same time the association with menstruation becomes less marked. At this stage the palpably dilated ducts and acini contain increased secretion, and an attempt should be made to remove it. Sometimes this may be effected by opening up the mouths of the ducts in the nipple by bathing with warm water and then applying a suction bell. This should be done systematically once a day, and a considerable quantity of turbid or greenish fluid may be removed in this way, and relief obtained. But, owing to occlusion of the ducts by fibrosis, the process may not be successful, so that the parts of the breast most affected may not be effectively drained, and the treatment should then not be persisted in for long. At the same time careful attention should be given to proper regulation of the bowels, and other possible sources of chronic intoxication, such as infected nasal sinuses, infected teeth, or cervicitis, must be sought for and treated. Any of these may interfere with the normal reabsorption of the secretion in a non-lactating breast, with consequent initiation or accentuation of pathological changes therein.

If none of these methods of treatment are effective, the use of X rays must be considered. The object of X ray treatment is the production of an artificial atrophy of the glandular epithelium with consequent inhibition of all secretory activity. The dosage required must be accurately gauged; usually one application by an expert radiologist results, after a temporary increase of pain, in considerable relief of symptoms. Sometimes a second application may be needed after an interval. This treatment must not be given if the patient is likely to become pregnant at a later date.

Chronic mastitis in its later stages is very often associated with the presence of cysts and with more than one form of epithelial overgrowth. A single small cyst may occasionally be satisfactorily treated by aspiration of its contents, but this is purely palliative. The cyst will probably recur, and it is nearly always the sign of diffuse, but less obvious, changes in the rest of the breast. If the cyst is large, or if several are present, operative treatment will have to be considered, since the application of X rays is not to be advised. It is a matter of experience that chronic cystic mastitis is less often associated with the presence of carcinoma than chronic mastitis without cysts, so that operation need not necessarily be regarded as imperative. Removal of one segment of a breast, or even local excision of a cyst, may occasionally be justified, but complete local amputation of the breast is usually to be preferred. The differential diagnosis between a localised chronic mastitis and an early carcinoma may be extremely difficult to make on clinical evidence alone, and if the slightest suspicion of the presence of a carcinoma has arisen, then an operation must be performed without delay. At the same time it may be remembered that chronic mastitis is not a "precancerous" condition in the great majority of patients in whom it occurs, so that the importance of operation on this theoretical ground need not loom too largely in the mind of the practitioner. No rules, however, can be laid down for guidance, for every case must be carefully considered on its merits.

## INTRODUCTION TO A DISCUSSION ON FRACTURES IN THE NEIGHBOURHOOD OF THE ANKLE-JOINT.*

BY HARRY PLATT, M.D. MANCH., M.S. LOND., F.R.C.S. ENG.,

SENIOR HON. SURGEON, ANCOATS HOSPITAL, MANCHESTER; CONSULTING ORTHOPÆDIC SURGEON, LANCASHIRE COUNTY EDUCATION AND PUBLIC HEALTH COMMITTEE.

A LITTLE more than 100 years ago Guillaume Dupuytren (1777–1835), then the foremost surgeon in France, writing on fractures of the lower end of the fibula, made one of his most illuminating contributions to the literature of our art.[1] From this essay, which represented the experience of a 15-year period as surgeon-in-chief to the Hôtel-Dieu in Paris, dates the real foundation of our present knowledge of the anatomy and the mechanism of production of ankle-joint fractures. Although injuries of this type must have been familiar problems in the practice of both of the ancients and of the surgeons of the Middle Ages, as Dupuytren himself pointed out, from the writings of Hippocrates, Ambroise Paré, and other great masters, scanty information is to be gleaned. But in the eighteenth century J. L. Petit (1674–1750), our own Percival Pott (1713–1788), and Cl. Pouteau (1725–1775)—all names to conjure with in the evolution of the surgery of fractures—began to teach that injuries which had long been classed as *dislocations* of the ankle-joint were always accompanied by *fractures* of one or both bones of the leg. This conception was adopted wholeheartedly by Dupuytren, and is emphasised in his *recognition of the fibular fracture as the pivotal* injury, with the dislocation as a consecutive phenomenon. It is interesting to compare his writings with those of another great surgeon of that generation—Astley Cooper—who has also left behind a masterly exposition of this subject, with the injuries described as primary dislocations, but from which the student of to-day can reconstruct every known variety of ankle-joint fracture.[2] In the introductory part of Dupuytren's *memoir* the serious disabling consequences of ankle-joint fractures are stressed in phraseology which leaves us in no doubt as to the type of functional result regarded as inevitable at that date. He writes as follows: "Under the most favourable circumstances they (i.e., fractures of the lower end of the fibula) almost always leave deformity and lameness, which renders progression more or less difficult or painful." (I quote from the admirable translation of Dupuytren's clinical lectures made for the Sydenham Society in 1846 by a bygone surgeon of St. Thomas's Hospital—Le Gros Clark.[3]) But Dupuytren saw no reason to rest content with contemporary standards of fracture treatment, and some idea may be gained of the therapeutic triumphs he achieved when we learn that in a personal series of 207 ankle-joint fractures 202 were "cured," and of these in *two* only was there deformity, and in *one* only loss of mobility! For an explanation of the five deaths in this series we must visualise the terrors of the compound fracture before the advent of the Listerian revolution.

Such quotations hold more than a purely historical interest for us. *Is Dupuytren's graphic description* of the sequelæ of ankle-joint fractures a mere echo from the past, or does it recall a type of disability with which we are still familiar? And to-day a full century since Dupuytren taught and perfected efficient methods of treatment, do his standards still prevail in the general handling of ankle-joint fractures? I think the answer is contained in the *deliberate choice of the subject for discussion at this* meeting. It is thus an old chapter in the history of surgery which we are about to reopen, and though our subject is a commonplace problem in surgical handicraft, classical in its antiquity, it appears strangely new as each succeeding generation comes fresh to its difficulties, often oblivious of the wealth of knowledge already bequeathed by the older masters.

### *Classification of Ankle Fractures.*

Ankle-joint fractures fall naturally into two distinct groups which have really little in common. In the *first* and more important group are the *fractures of the leg bones*—lower end of the tibia and fibula; the *second* comprise fractures of the *astragalus*. As *a rough indication of the relative incidence of the* two groups of lesions, I might quote some personal statistics. In the four-year period, 1921–24, in which I have reviewed for the purpose of this paper the *recent* ankle-joint fractures treated in my own clinic, there have been 116 fractures of the leg bones and four fractures only of the astragalus. In the first nine months of this year (1925—January to September), 29 recent ankle-joint fractures have passed through my unit at the Ancoats Hospital, but all belong exclusively to the first group. Fractures of the astragalus are thus comparatively rare injuries. They have a certain intrinsic interest, but from an ætiological and mechanical point of view would be more appropriately studied with fractures of the os calcis. We shall now consider the two groups separately, devoting the greater part of our attention to the fractures of the leg bones.

### *Fractures of the Leg Bones (Tibia and Fibula).*

*Nomenclature and Classification.*—Much confusion surrounds the current nomenclature of ankle fractures, for at least three different types of terminology are commonly employed. In the first place, there is the *historical* classification, in which the name of some great surgeon of the past has become attached to a particular type, or group, of fractures—e.g., Pott's fracture, Dupuytren's fracture. Then there is the classification based on the *mechanism of production*, as illustrated in the use of such terms as abduction fracture, adduction fracture; and, lastly, many attempts have been made to evolve a grouping with a strictly *anatomical* or *physiological* foundation—e.g., bi-malleolar fractures, isolated fractures of the fibula, and so on. It is desirable in the interests of surgical teaching that the scope of such varied terminology should be defined and, if possible, some simple standardised classification adopted for general use.

1. *Historical Nomenclature.*—It is often stated that Pott obtained first-hand knowledge of the fracture with which his name has become inseparably associated as a result of a personal accident. But this is untrue, for the injury sustained by Pott was a fracture of the shaft of the tibia—probably with little or no displacement, and from which he made an excellent recovery.

In the course of a general essay on fractures of the leg bones and their treatment, a description of what Pott believed to be the common ankle-joint fracture was given, accompanied by an illustration which is now classical[4] (Fig. 1). It will be seen that this injury consisted in a *transverse* fracture of the fibula about 2½ inches above the malleolar tip, combined with a rupture of the internal lateral ligament and a conspicuous outward displacement of the foot. Pott gave a logical account of the mechanism of the eversion deformity, which in his view was due to the mechanical advantage obtained by the peronei muscles as soon as the support of the fibular strut was lost. It is also clear from his writings that he had treated such injuries with success, reducing the deformity after flexing the knee and placing the limb on its outer side. Dupuytren (loc. cit.), writing 50 years later, whilst applauding Pott's description, expressed the opinion that the English surgeon did not employ appropriate retentive treatment.

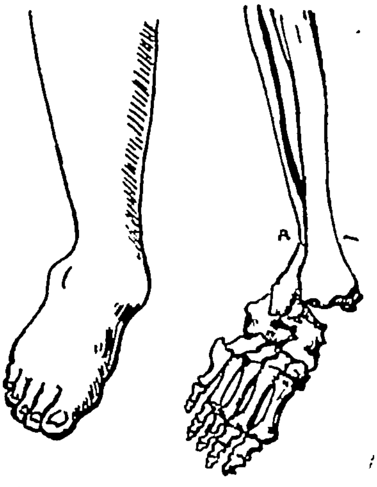
---

* The discussion took place at the annual meeting of the British Orthopædic Association, Manchester, on Oct. 23rd, 1925. In a forthcoming issue of THE LANCET will be given further contributions to the discussion. The illustrations to Mr. Platt's paper, with one exception, are the work of Dr. Margaret Greg, of Manchester, and for the most part are accurate line drawings of radiograms.

It is now evident that as a description of the common ankle-joint fracture Pott's account and illustration contain several anatomical inaccuracies. Indeed Ashhurst, of Philadelphia,[5] who has given us the most authoritative essay on ankle-joint fractures of modern times (1922), declares that Pott depicted a type of fracture which does not exist! Dupuytren appeared, however, to accept Pott's description as a sufficiently faithful picture of the common fracture of the lower end of the fibula accompanied by displacement of the foot, an injury which dominated his own series of 207 ankle fractures. To this familiar lesion the French have given the name Dupuytren's fracture. Unfortunately in English surgical literature the term Dupuytren's fracture is applied to a fracture of the fibula with complete diastasis at the inferior tibio-fibular junction, and gross displacement of the astragalus which follows the distal fibular fragment and comes to lie in contact with the lateral aspect of the tibia. This is an exceedingly rare lesion, which Dupuytren himself saw *once* only in a series spread over a period of 15 years. We should therefore agree to eliminate the Dupuytren fracture of the English text-books as a term denoting a definite *group* of lesions (see Fig. 8). According to Ashhurst, the first accurate description of the typical ankle fracture recognised clinically both by Pott and Dupuytren is to be attributed to Maisonneuve[6] (1840), who established the great frequency of the *oblique* fracture of the lower end of the fibula and its production by pure *external rotation* of the foot on the leg.

It is obvious that it will be difficult, if not impossible, to abolish the term "Pott's" fracture, in this country at least. It would therefore seem best to adopt some broad definition of its scope. There is little objection to its employment as a generic title, to include those fractures of the lower 3 inches of the fibula, which are accompanied by rupture of the internal lateral ligament or fracture of the internal malleolus, and in which there is the slightest degree of deformity at the ankle-joint—either eversion alone or eversion combined with posterior displacement of the foot. But at the same time it would be more generous, and historically more accurate, to speak of fractures of the *Pott-Dupuytren* type. This is the terminology which will be adopted in this paper.

FIG. 1.

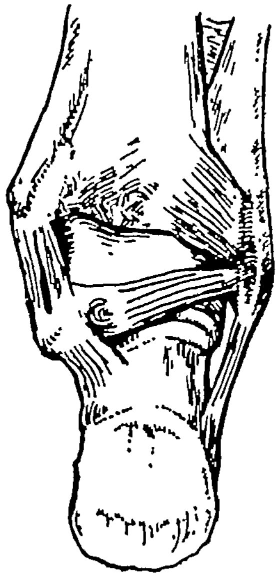


Copy of Pott's original illustration.

2. *Mechanism of Production.*—The mechanism of the production of ankle fractures must receive our close attention quite irrespective of any attempt to establish a working classification. The older surgeons first approached this problem from the experimental standpoint in the production of ankle fractures on the cadaver, notable contributions being made by Maisonneuve (1840), and, later, Tillaux[7] (1872), and Honigschmied[8] (1877).

*Ankle-joint Mortise.*—The physiological mechanics of the mortise formed by the lower ends of the tibia and fibula should need little elaboration. Certain points, however, may be emphasised. (1) Although the two bones are bound together by the strong ligaments of the inferior tibio-fibular junction, the mortise exhibits an appreciable degree of elasticity which is called into play as the astragalus is thrust back during dorsiflexion of the foot. (2) The stout connexion maintained between the fibula and the astragalus by the posterior fibres of the external lateral ligament of the ankle has no counterpart on the mesial aspect of the joint. In consequence, in all injuries in which the tibio-fibular continuity is lost, the astragalus remains attached to the fibula and is displaced with it (Fig. 2). (3) Backward displacement of the foot cannot occur until the fibula is freed entirely from the tibia, or alternatively the astragalus is freed from the external malleolus. The latter contingency does not arise in ankle-joint fractures.

FIG. 2.



Right ankle-joint (posterior view). Shows the strong fasciculus of the external lateral ligament which binds the external malleolus and astragalus together.

*Types of Violence.*—A study of the mechanism of production of ankle fractures resolves itself mainly into a consideration of the effects of the different types of *indirect violence*, for fractures in this region due to direct violence are extremely rare and possess little special interest (1 per cent., Ashhurst). There are three types of forced movement of the foot in which a breaking strain may be transmitted via the astragalus to the lower ends of the tibia and fibula. These are; (1) external rotation; (2) abduction (eversion); (3) adduction (inversion). To these may be added a fourth type of violence which often acts as a contributory factor—viz., an upward compression thrust on the ankle mortise.

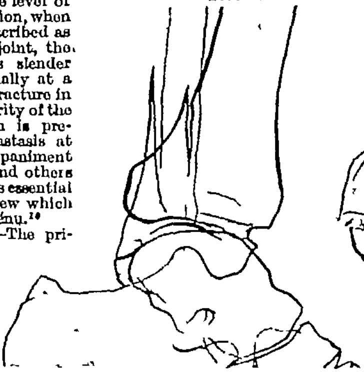
1. *External rotation* as a form of indirect violence, in contradistinction to abduction, was first investigated by Maisonneuve, who from his experiments on the cadaver believed it to be the means whereby the common type of ankle-joint fracture was produced. In this movement the foot is rotated out in the ankle mortise around the vertical axis of the leg, and the force transmitted to the fibula is a *torsion* strain which breaks this bone in an *oblique or spiral fashion*, the line of fracture running downwards and forwards through the inferior tibio-fibular joint (Fig. 3). The ligamentous bond between the tibia and fibula for the greater part remains intact, so that in this fracture *diastasis* is rare. The fibular fracture is the pivotal injury and at this stage the violence may be completely expended. (The so-called fracture of the first degree.) But when the external rotation force continues to act certain consecutive lesions are induced—either a fracture of the internal malleolus, or its equivalent, rupture of the internal lateral ligament. (Fracture of the second degree (Fig. 4).) In a few extreme cases the tibial lesion is represented by a fracture which involves the whole width of its lower end. (The third degree fracture (Fig. 5).)

2. *Abduction* (eversion).—Force abduction of the foot tends to evert the astragalus in the ankle mortise, and so exercises a *bending* force on the lower end of the fibula. If the fibula breaks, the lesion shows all the characteristics of a bending or flexion fracture—i.e., the line is roughly transverse, and on the concave aspect there may be a localised comminution with partial detachment of a small wedge. Here, again, the

same forced movement tears off the inner malleolus. I have put the fibular fracture first, but chronologically the *internal malleolus* gives way before the fibula breaks. Three degrees of fracture again may be distinguished as in the external rotation fractures. In the torsion fracture produced by external rotation the site of the lesion is remarkably constant. But the abduction fracture may occur either (*a*) below the level of the inferior tibio fibular junction, when the fracture is accurately described as *malleolar*, or (*b*) above this joint, the fibula breaking through its slender "surgical" neck, or occasionally at a still higher level. With a fracture in the former situation the integrity of the inferior tibio fibular junction is preserved, but in the latter diastasis at this joint is the usual accompaniment (Fig 6) Destot,[9] Ashhurst and others regard preliminary diastasis as essential in this type of fracture, a view which has been controverted by Quénu.[10]

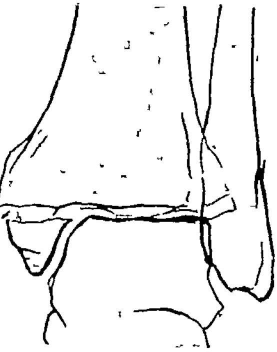
3 *Adduction* (inversion)—The primary lesion induced by a forced adduction (tibial flexion) is the tearing off of the *external* malleolus The continued compression thrust of the astragalus against the internal malleolus adds on a secondary fracture But as Dupuytren showed, the associated *tibial* injury may be produced in a different way—viz., by weight-bearing immediately following the occurrence of the fibular fracture. In such cases the line of split may begin well within the mortise and emerge on the mesial aspect of the tibial shaft just above the ankle.

FIG. 3.



External rotation fracture Lateral radiogram. Shows the oblique fracture of the fibula and a *posterior marginal fracture* of the *tibia*.

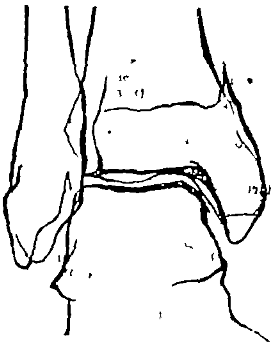
FIG. 4.



External rotation fracture Antero-posterior view. Note the separation of the internal malleolus The fibular fracture is scarcely visible.

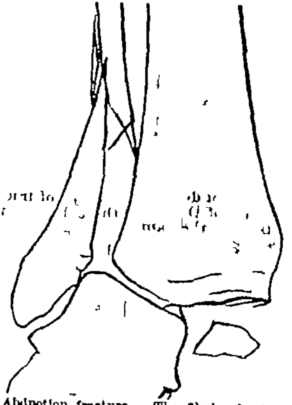
The relative incidence of the three forms of indirect violence has long been a matter for investigation and conjecture. Dupuytren surmised that 60 per cent. of his ankle fractures were produced by an *adduction* force, but he commented on the difficulties of obtaining accurate information from patients. This question has received greater elucidation since the introduction of radiography. Ashhurst, in an analysis of 300 cases, found *external rotation* fractures in 61 per cent., *abduction* fractures in 21 per cent., and *adduction* fractures in 13 per cent. His conclusions have been deduced from a careful scrutiny of the radiograms of his series which showed a preponderance of the oblique or spiral fracture of the fibula. In my own smaller series of recent ankle-joint fractures (110 cases) much the same relative incidence is seen. One finds, however, with Ashhurst, that the radiographic interpretation of a certain proportion of fibular fractures is difficult; and it is a matter of personal opinion whether these should be assigned to the external rotation or abduction class

FIG 5.



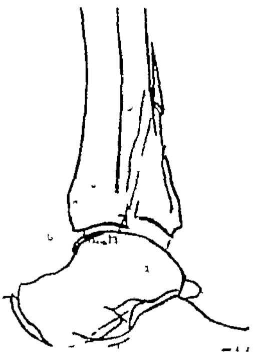
External rotation fracture (third degree) (after reduction). The tibial fracture includes *the whole* width of the lower end.

FIG 6.



Abduction fracture The fibular fracture of the "bending" type is unusually high. There is an *accompanying* diastasis.

FIG 7.

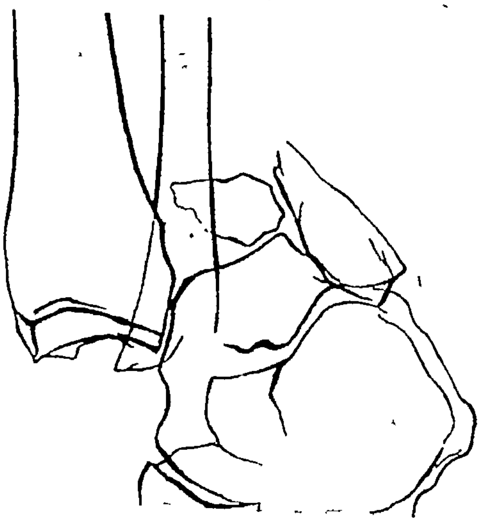


External rotation fracture Shows accompanying posterior marginal fracture of the *tibia*.

4. *Compression Violence.*—In the mechanism of ankle fractures the rôle of another important factor remains to be considered—i.e., the effect of weight borne on the injured limb immediately following the solution of continuity of the fibula. An illustration of the intervention of this factor has already been quoted in connexion with the adduction The effect of body-weight is first of all to

the fibular fracture more completely, and so produce or enhance the eversion displacement of the foot. But in a certain proportion of ankle fractures this upward compression force is responsible for the production of a third fracture known both to Dupuytren and Astley Cooper, later forgotten, and rediscovered by many subsequent observers. This is now often called the *posterior marginal fracture* of the tibia. This fracture involves the separation of a triangular fragment from the posterior aspect of the tibia in the neighbourhood of the inferior tibio-fibular junction, the line of fracture running down into the roof of the mortise. The fragment remains indissolubly attached to the external malleolus, and is displaced with it in company with the astragalus (Figs. 7 and 8, A). Much attention has been paid to the incidence and the mechanical significance of the posterior marginal fracture, particularly by modern French writers—e.g., Chaput,[11] Destot (loc. cit.), Quénu (loc. cit.). Lucas-Championnière [12] was first responsible for the suggestion that it is produced by a crushing force acting upwards. This important consecutive injury is by no means a rare complication of ankle fractures. Ashhurst discovered 58 examples in his series of 300 (19 per cent.), and other writers—e.g., Destot, Quénu, and Speed [13]—have found it in roughly 10 per cent. of their cases.

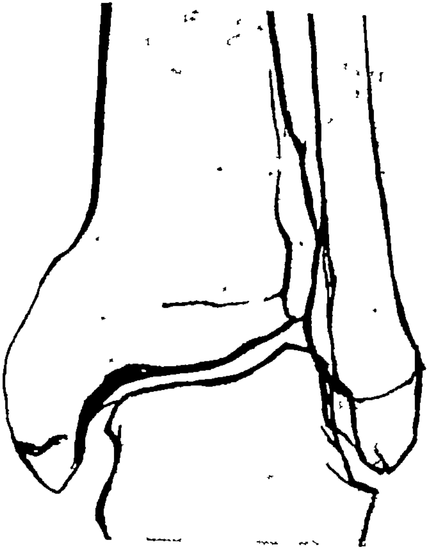
FIG. 8, A.



Combined fracture of both bones with extreme backward and outward dislocation. Note that the fibula remains attached to the astragalus, and the presence of a posterior marginal fracture of the tibia.

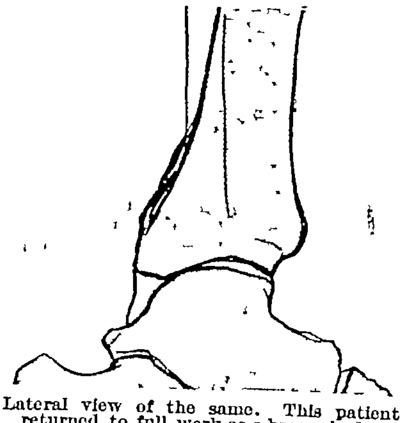
It is interesting to note that this fracture may occasionally be present as an isolated lesion unassociated with the classical fibular injury (Meissner,[14] Ashhurst). Ordinarily it is to be discovered in a high proportion of external rotation or abduction fractures of the fibula in which there is gross displacement of the astragalus (Potts-Dupuytren type). It is to be remembered, however, that this fracture is often visible in radiograms where displacement is practically non-existent (see Fig. 3). Although posterior dislocation of the foot may occur in the absence of a posterior marginal fracture—i.e., where tibio-fibular diastasis has occurred (see Figs. 10, A, 10, B)—for practical purposes the deformity and the lesion are interdependent. This is well illustrated in skiagrams of many mal-united ankle-joint fractures (Fig. 9). An interesting example of backward displacement of the foot in an isolated fibular fracture, uncombined with a posterior marginal fracture or diastasis, has been recorded recently by Clavelin,[15] but in this case the fracture was produced by direct violence. There remains yet another consecutive fracture which on rare occasions may contribute to the anatomical picture of the typical ankle fracture. We have already referred to the occurrence of diastasis between the tibia and fibula in a certain proportion of abduction fractures. Usually this separation between the bones implies a pure rupture of the interosseous ligaments, but more rarely an *anterior marginal fragment* is detached from the tibia including what is known as the anterior tubercle. Diastasis by fracture may in exceptional circumstances be associated with external rotation fractures, where chronologically it is believed to precede the fibular break (Ashhurst). The anterior marginal fracture also may be represented by a mere crack with no actual displacement.

FIG. 8, B.



The same ankle six months after manipulative reduction, 1921. Antero-posterior view.

FIG. 8, C.



Lateral view of the same. This patient returned to full work as a brewer's drayman eight months from the time of the fracture, and has worked continuously without symptoms of discomfort for the past three years.

3. *Anatomical and Physiological Classifications.*—Elaborate classifications of ankle-joint fractures have been evolved by Destot (1911) on a physiological basis, by Quénu on an anatomical basis (1912), and a simpler combined scheme suggested by Tanton in 1916.[16] Ashhurst (loc. cit.), whilst advocating a classification founded on mechanism, also presents an anatomical grouping as illustrated by his own material. For practical purposes a very simple classification is desirable, such as the following which is based on Tanton's more elaborate scheme.

*Fractures of the Malleoli.*—(1) Isolated. (*a*) Fibula, (*b*) internal malleolus. (2) Combined. (*a*) Low bi-malleolar, (*b*) Pott-Dupuytren type.

*Fractures of the Tibial "Pilon"* † (i.e., weight-bearing articular portion). (1) Isolated. (*a*) Anterior marginal, (*b*) posterior marginal, (*c*) "T"- or "Y"-shaped, (*d*) atypical fractures, (2) Associated (with malleolar fractures).

---

† This is a term suggested by Destot.

This classification is capable of expansion for statistical purposes, and at the same time is simple enough for the maintenance of routine records in the work of a fracture clinic. Some such broad grouping is also necessary for use in undergraduate or post-graduate teaching, which in my judgment should be founded on an exposition of the mechanism of production as a natural approach to the study of the principles which govern efficient treatment. For this purpose the classification of Ashhurst is invaluable.

*Incidence of the Various Anatomical Types.*—Now that we have chosen from the available terminology some sort of practical grouping for ankle-joint fractures, it is instructive to inquire into the relative incidence of the various anatomical types. Ashhurst's series and my own lend themselves readily to such a survey.

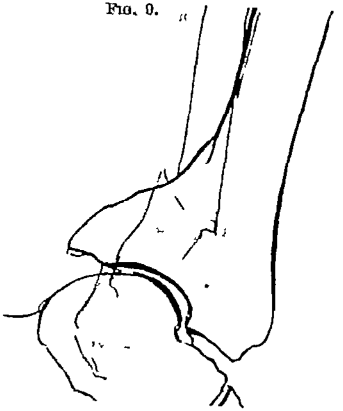
| | Ashhurst | | Platt.* | |
|---|---|---|---|---|
| Fractures of malleoli . | 300 cases. | | 116 cases. | |
| | Per cent. | | Per cent. | |
| Isolated—Fibula . | 35 | | 28 | |
| Int. malleolus | 6 | | 12 | |
| Combined—Low bi malleolar | 8 | 53 | 8 | 55 |
| Pott-Dupuytren | 45 | | 47 | |
| Fracture of the tibial "pilon"—Isolated . | 2 | | 3 | |

* In this series the tibial fracture was represented by a so-called epiphyseal displacement in *three* cases.

Kellog Speed's (loc cit.) series of ankle fractures reviewed in 1914 is more difficult to analyse on the above basis, as under the heading bi malleolar he includes many lesions which we should assign to the Pott-Dupuytren class His figures for the combined group of malleolar fractures, however, give a percentage which roughly corresponds to the incidence shown in the above table

It is evident that in any consecutive series of ankle-joint fractures approximately 50 per cent. of the cases will be combined lesions of both bones.

FIG. 9.

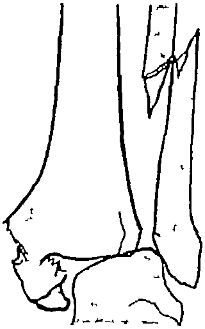


Malunited ankle fracture of six years' standing The demarcation between the posterior marginal fracture and the remainder of the lower end of the tibia is still visible

Moreover, it will be found that the predominating fracture of the fibula is the oblique or spiral type induced by external rotation.

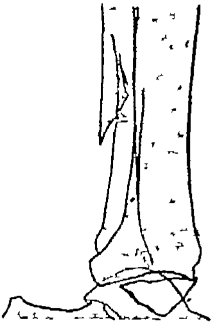
*Incidence of Primary Deformity.*—We must also realise that in the majority of ankle fractures there is no appreciable displacement of the astragalus. I make this statement with extreme diffidence, not unmindful of the finer degrees of mal-alignment of the fibula, internal malleolus, or astragalus, which radiograms often display (see Figs. 4, 7). In both Ashhurst's and my own series fractures with definite and unmistakable clinical displacement constitute at least *25 per cent of the whole*, and the same conclusions may be derived from the figures of Speed and other writers. But I am convinced that a more careful scrutiny of the combined fractures of the tibia and fibula in the future will reveal a higher incidence of primary deformity.

FIG. 10, A.



Abduction fracture Antero-posterior view The fibular fracture is unusually high. Diastasis is present.

FIG. 10, B.



Lateral view of the same fracture. Note the backward displacement of the astragalus.

## *Clinical Considerations.*

The conditions under which ankle fractures are produced, and the resulting clinical picture, are sufficiently familiar to render a detailed consideration unnecessary Bearing in mind the high proportion of fractures in which obvious primary *deformation* is non-existent and crepitus not readily obtainable, we cannot insist too often on the necessity of a full radiographic examination of all ankle injuries in which the type of violence is a forced movement of the foot. Skiagrams in two planes are, of course, a sine qua non. The typical external rotation fracture of the fibula may be barely discernible in an antero-posterior view, but is always well shown in a lateral view (see Figs. 3 and 4)

In a *patient seen* for the first time a few hours after the accident, minor degrees of displacement may be masked to some extent by the effusion in or around the ankle-joint. *In my opinion* the vital importance of the early recognition of the lesser degrees of displacement is not widely appreciated. Such cases tend to become the *victims of a laissez-faire* attitude on the part of the medical attendant, be he junior hospital officer or general practitioner. A radiographic examination is often postponed *for* a few days, and the skiagrams when obtained are interpreted hastily as showing no gross displacement, so that there appears to be no indication for *manipulative* reduction under anæsthesia. Such limbs are occasionally laid on a pillow and early *passive* movements instituted—an example of the common modern abuse of the teachings of Lucas-Championnière.

The ankle fracture with gross eversion and backward dislocation of the foot, with the skin tightly stretched over the internal malleolus, offers little or no difficulty in diagnosis even to the uninitiated. Paradoxically enough such cases are *often handled* more effectively than those in which a minor displacement is present.

### *Treatment.*

In the treatment of ankle fractures two distinct problems must be envisaged: (1) the treatment of recent fractures; (2) the treatment of old fractures giving rise to deformity and disability.

*Recent Fractures.*—At this stage in the introduction to our discussion the first great point for debate emerges. This is concerned with the relative merits of *conservative* and *operative* methods of treatment. It will be generally agreed that in the large group of fractures unaccompanied by appreciable displacement the employment of conservative measures as a routine is beyond criticism. Our attention must therefore be focused on the smaller group which shows the typical primary displacement. The economic importance of such injuries when occurring in adults who are in the prime of life is sufficiently obvious.

It is probably true to say—as I have already hinted—that the disabling sequelæ of ankle fractures are as familiar to-day as in the time of Dupuytren. Such results do not warrant a general indictment of conservative treatment. They are simply evidence either of gross neglect, which usually implies a missed diagnosis, or the imperfect application of methods of reduction and retention which may be inherently sound. The questions to be answered are: (1) Is it possible by manipulative measures alone to obtain accurate reduction of the displacement and to control the limb effectively by external fixation for the necessary period of healing of the fracture? And (2) in actual practice do such methods give the highest standard of functional results? If conservative measures are found wanting in any single particular, the arguments in favour of primary operative interference are likely to be overwhelming. It may be remarked here that the teaching of the Arbuthnot Lane school[17] has not met with ready acceptance, as far as ankle-joint fractures are concerned. I have made some attempt to answer these questions, and to define my own attitude in this discussion, chiefly as a result of a survey of the personal series of fractures already quoted, and also from the collateral experience over a longer period of a considerable number of similar fractures not systematically recorded.

When I began to take an intensive interest in this subject some three years ago, stimulated particularly by Ashhurst's unique paper, my general impression was that the routine use of non-operative methods was attended by far too many disappointments. At that time I felt tolerably certain that sooner or later I should be persuaded to give a systematic trial to reduction and fixation by open operation. This attitude was chiefly determined by the fact that the majority of the patients with recent ankle-joint fractures dealt with in my clinic were discharged from physiotherapeutic treatment somewhere between the eighth week and sixth month, according to the type of case.‡ At this stage most of them were considered fit to undertake light work. In many cases the records made at the time of discharge emphasised the existence of a slight limp, necessitating the use of a stick, and many ankle-joints which showed a satisfactory anatomical result were not entirely free from discomfort, and sometimes showed limitation of mobility. But my earlier impressions have been considerably modified by the information obtained from a survey of the late results, for it has been the rule to find that steady improvement has occurred from the sixth month onwards. I have been able to trace about 90 per cent. of the cases, and to estimate the type of functional result either from a personal examination or from the answers given in a questionnaire. The most striking results are seen in the patients reviewed after a period of two years or more has elapsed from the time of the injury, the great majority of whom have been able to return to pre-accident occupations involving laborious duties (see Fig. 8, A, B, C). No patient in this series is prevented from working as a result of his injury.

I am confident that in the greater proportion (if not all) of ankle-joint fractures accompanied by displacement even of the most extreme degree, it is possible by non-operative methods to achieve perfect anatomical reposition, and to ensure the highest standard of functional result. Similar views have been emphasised recently by Ferry of the Strasbourg University Surgical Clinic.[18]

Of the 116 cases reviewed in my series, conservative methods have been employed in all but four, which were treated by open reduction between the fourth and sixth week following the injury. In two of these no previous attempt had been made to correct the primary displacement; in the remaining two manipulative reduction carried out in my own clinic, and for which I accepted responsibility, failed to give perfect readjustment. These operations do not really belong to the category of deliberate primary operative reduction, but they illustrate in my judgment the true rôle of operative methods in the treatment of recent ankle-joint fractures—i.e., that one should be prepared to resort to operation only if manipulative reduction—repeated if necessary—has failed, or where displacement has been left uncorrected for some days.

### *The Technique of Manipulative Reduction.*

The method used in my own clinic has been correction of the displacement under full anæsthesia at the earliest possible moment, followed by the immediate application of a well-fitting plaster-of-Paris cast with the posterior part of the foot fully inverted. I believe that it is difficult to effect perfect readjustment in the majority of these fractures except under conditions of complete muscular relaxation; and further, in my experience, there is no form of retentive apparatus, other than plaster-of-Paris which gives adequate control of the heel once correction of the eversion and backward dislocation has been achieved. In hospital practice the primary reduction of a Pott-Dupuytren fracture must of necessity often fall to the lot of the surgical residents. It is only where there is a segregation of fractures that residents can hope to acquire dexterity and confidence in the handling of these injuries. In the fracture organisation of my own hospital, the resident surgical officer (a senior "long-stay" resident) and the house surgeon attached to my unit are conjointly responsible for the control of all fractures once they reach the casualty department. Many of the ankle fractures are reduced and are fixed in plaster before I see them. In such cases it is a strict rule that the radiograms taken after reduction must be submitted to me for approval. I find it necessary to emphasise unceasingly the importance of the minor degrees of displacement and the advantages of prompt reduction in all cases.

*After-treatment.*—It is unnecessary for me to enter into a detailed exposition of the technique of after-treatment. This aspect will probably be elaborated in the discussion which is to follow. It is my usual practice to bivalve the plaster cast at the end of three weeks, or even earlier in the slighter cases, but to retain the foot in the inverted position in the posterior half of the plaster two or three weeks longer. At this stage light massage, active movements of the toes, and, according to the surface area available, graduated faradic stimulation of the muscles of the anterior tibial group are carried out. The posterior half of the cast may with advantage be worn for some little time as a night splint. When the limb is left entirely free from restraint, more energetic physical methods are employed, but forced movements of the ankle-joint are, of course, prohibited. Where there is an unusual persistence of œdema or pain, radiant heat or diathermy are prescribed. Before weight-bearing is tried—from the tenth week onwards—the classical precautions to prevent secondary deformation are adopted—viz., the wedging up of the inner border of the shoe, and, in patients of heavy build, the application of a short outside steel and "T"-strap. This is worn for some six months. The final stage in the physiotherapeutic régime is gymnasium treatment given in the "ankle class."

---

‡ The average period of full incapacity was 14 weeks.

*Old Fractures.*—During the four-year period chosen for a review of my recent ankle fractures, a series of 50 old ankle fractures treated elsewhere, and presenting some form of disability, have passed through my hands. It is interesting to find that the majority of these showed malunion with well-marked deformity, which points to the conclusion that given a good anatomical reduction the functional result is rarely unsatisfactory.[1] This series contained, however, a few patients with painful ankle-joints showing a certain degree of limitation of mobility, but with no trace of mal-alignment. In a considerable number of the cases of gross malunion, there was free mobility at the ankle. The deformity generally appeared to have been determined by imperfect reduction, rather than neglect in after-treatment, although no doubt the latter factor played a contributory rôle.

In the treatment of the disabilities which may follow ankle fractures we are called upon to choose between mere *palliation* and the use of *operative measures.*

(*a*) *Palliative treatment* is often the only method available, by reason of age, physique, or the economic situation of the patient. In cases with deformity much comfort is derived from the wearing of the usual outside steel and "T"-strap; but this appliance must be a permanency. For the painful ankle-joint, which is most probably the seat of an early osteo-arthritis, we are compelled to rely on the usual analgesic physiotherapeutic measures which are only too often disappointing.

(*b*) *Operative Treatment.*—In younger individuals the advisability of operative reconstruction of the fracture should always be seriously considered. The choice of operation must be based on the pathological anatomy of the fracture in each individual case.

Several types of operation may be briefly reviewed. (*a*) For malposition in the intermediate stages before union is complete, or some months after the injury, correction should be obtained after cutting through the line of the fractures in both fibula and tibia. (*b*) In long-standing cases with a pure eversion deformity, a *linear osteotomy* of the fibula combined with *cuneiform* resection of the *tibia* allows accurate restoration of the axis of the astragalus. (*c*) In long-standing cases with gross backward displacement of the foot showing the posterior marginal fracture, in addition to an osteotomy of the tibia and fibula, the projecting tibial block should be freely excised (see Fig. 9). (*d*) In a certain proportion of old cases with extreme deformity and pain, the reconstructive operation will resolve itself into an *arthrodesis* of the ankle-joint.

The cosmetic and functional results of the reconstructive operations for old Pott-Dupuytren fractures are variable. After the correction of an eversion deformity, in which free mobility of the ankle-joint is retained, the results are most gratifying. But where there is a bony block at the ankle, in my experience it is rare to be able to restore reasonable mobility. *Speaking generally, one finds that correction of deformity is followed by a relief from pain.* As in the recent fractures, adequate after-treatment is essential.

This brings to a conclusion our survey of the first group of ankle fractures, and before proceeding to introduce the second group I would suggest that in the discussion to follow extended debate is desirable on the following points: (1) The general standards of functional result obtained by conservative methods of treatment. (2) The rôle of operative interference in recent fractures. (3) The technical minutiæ of manipulative methods of reduction and retention. (4) Types of reconstructive operation applicable in the old fractures, and the general results obtained.

### *Fractures of the Astragalus.*

Owing to their comparatively low incidence in ankle-joint fractures as a whole, *fractures of the astragalus* do not lend themselves so readily to a broad presentation. It is well known that they occur either as *isolated lesions* or in *association* with injuries of other tarsal bones, and more particularly in combination with fractures of the os calcis. A simple anatomical grouping divides these injuries into (*a*) fractures of the body and (*b*) fractures of the neck. The mechanism of production is simple—viz., the upward compression thrust of a fall from a height on to the heel. The resulting disturbances may involve (1) the ankle-joint; (2) the astragalo-scaphoid joint, or (3) the subastragaloid joint. In the latter event the mechanical problems are those presented by the os calcis fractures, and therefore lie outside the scope of this discussion.

*Treatment.*—In the treatment of *recent* fractures of the astragalus it is impossible to lay down hard-and-fast rules. Each fracture must be considered on its merits. Conservative measures, in the earlier stages at least, are likely to prove effective. But where there is gross primary distortion of the astragalus, with the certainty of a future bony block at the ankle, operative interference must be contemplated.

*Old fractures* of the astragalus, giving rise to pain, deformity, and loss of mobility, are seen from time to time.

Such disabilities may be dealt with by appropriate operative treatment, which will generally include either the resection of a bony block (partial or total *astragalectomy*), or, in a few extreme cases, the surgical fixation of the painful and deformed joint (*arthrodesis*).

### *Conclusion.*

The subject of ankle-joint fractures is now before the meeting, and the points which appeal to me as worthy of special consideration have already been emphasised. The success of the discussion which is to follow will be measured not merely in terms of the brilliant results achieved by a few individual surgeons, specially gifted or fortunately placed, but rather in the impetus it may give to a renewed effort to improve the general standard of the treatment of such injuries. We are undoubtedly on the eve of a renaissance in the organisation and treatment of fractures, a movement which especially concerns the members of this Association. Let us confidently hope that soon the century-old dictum of Dupuytren will lose its sting, so that in speaking of ankle-joint fractures it may never be said that "under the most favourable circumstances they almost always leave deformity and lameness, which renders progression difficult or painful.".

# THE DOCTOR'S MOTOR-CAR.

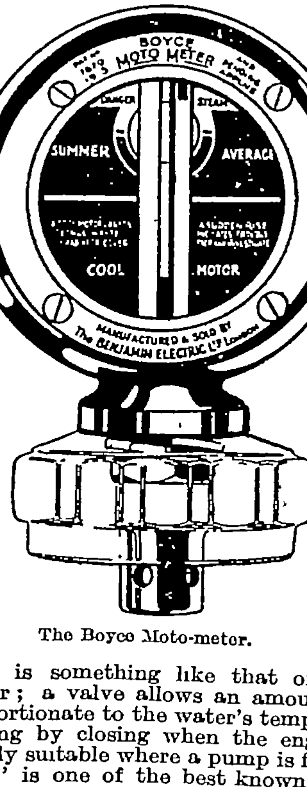
(FROM OUR MOTORING CORRESPONDENT.)

### *Cold Weather Accessories.*

MOST engines are difficult to start in cold weather, and hardly any are now fitted with priming-taps. Flooding usually makes matters worse, as it fills the combustion-spaces with liquid petrol. The new Lodge priming plug, costing only 2*s.* 0*d.* more than the ordinary sparking plug, with a screw-off head, is, therefore, an extremely useful invention, for all cylinders can be primed without removing the high tension leads in a few minutes.

This concerns cold engines, but practitioners who have to be ready to take the car out at short notice cannot really afford to let their engines go cold. Unless some method is available of protecting the car from frost at night the circulating system must be drained, and to fill it up again requires time. There are, broadly speaking, three methods of keeping the water warm: bonnet lamps, garage stoves, and water pipes. The last are expensive and can only be fitted by a builder and decorator; oil stoves are perfectly efficient in a small garage and cost about two guineas; Davy lamps to hang inside the bonnet cost about 20*s.* There are also bonnet lamps lit from the house-current, and an ordinary carbon filament bulb gives a good heat, but electricity costs more than paraffin or even petrol for this purpose. A hot fomentation on the induction pipe, by the way, enormously facilitates starting.

FIG. 1.

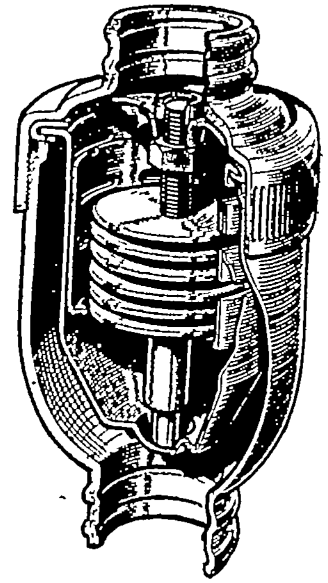


The Boyce Moto-meter.

Every car should have a radiator-muff made to fit it, with a flap that will allow the cooling-space to be varied. Any accessory dealer can have this done, and several dealers have stocks of muffs to fit all well-known makes. A radiator thermometer which costs a guinea (Fig. 1), is useful, since when the water temperature is known it can be regulated with the muff to the point which gives the most efficient running. Muffs cost about 15*s.* for small cars and 30*s.* if they cover the whole bonnet. The "thermostat," or automatic regulator of the water temperature, was, until recently, confined to the most expensive of cars; now it is made for about 30*s.* and fits into the rubber pipe between the radiator and the outlet. The principle is something like that of the aneroid barometer; a valve allows an amount of water to pass proportionate to the water's temperature, and retards cooling by closing when the engine is stopped. It is only suitable where a pump is fitted. The "motorstat" is one of the best known (Fig. 2). It works by means of multiflex bellows filled with a volatile liquid which is sealed in hermetically. When the temperature of the surrounding water rises, more of the liquid vaporises, thus the bellows expand when the water is hot and contract when it is cold. The action of expansion or contraction is communicated to a valve which governs the flow of water.

Cold weather troubles are not confined to the engine. Rain on the windscreen is bad enough, but sleet or snow may almost blind the driver. Before the days of windscreen wipers there were various preparations sold which would prevent water from staying where they had been applied, and they usually kept the view very much clearer than the rubber squeegee. There is now, however, a cheap wiper called the "Desmo," the rubbers of which are fed with some solution from a little reservoir. This should give a clearer view than bare rubber, besides needing far less operation, as one sweep will do for an hour or so, unless it is snowing. Failing any fitted device the cut surface of a raw potato or of an apple rubbed over the glass gives some temporary relief.

FIG. 2.



The Motorstat, showing the bellows and the passages through which water flows.

### *Chassis Lubrication.*

In the handbooks that they issue with their cars, makers instruct the owners to lubricate some bearings every 200 miles, some every 500 and some every 1000—and so on. It would be interesting to know whether there exists an owner so conscientious and obedient as to follow in detail these instructions. Chassis greasing has been immensely simplified since the introduction of the Enots, Tecalemit, and other systems, in which a set of nipples is fed by a grease-gun, but even this process takes a fair amount of time. Many busy practitioners grudge the time given to anything connected with maintenance of a car, and some of them never touch a grease-gun till they hear a squeak, and perhaps not even then. By the time a bearing squeaks, however, it has begun to wear very badly, and no amount of greasing afterwards will make up for the damage already suffered, and so the prudent owner-driver, however rushed, must make a compromise. Not all parts need the same attention. There are roughly three classes: those in constant motion, those in intermittent motion, and those that move only occasionally. The gear-box and back axle give little trouble, as they usually have large openings. It does not pay to over-grease, but at the same time the lay-shaft and crown wheel respectively must dip well into the lubricant, and inspection once a fortnight should be ample. The main universal joint, just behind the gear-box, and (if the gear-box is away from the engine) the clutch-shaft universal joints are liable to be forgotten. These parts are under constant stress and friction and cause a very unpleasant backlash when they get worn; they should be kept full of grease, which means replenishment at least every fortnight. The most important units are the springs, because there is nothing so irritating and so difficult to remedy as a spring squeak. If they are of the short "quarter-elliptic" type there is no greasing to do, but if they have shackles they must be greased thoroughly every week. It makes for easy riding to keep the gaiters full as well. The same applies to the steering, for this is also under intermittent stress and gives bad trouble if it gets loose

The brakes are about the only mechanisms that can be neglected for long periods with any degree of impunity, for they move so little that there is no particular danger in waiting for a squeak. It is not advisable, however, to neglect any part, and when one pedal has to work four brakes the less friction it encounters the better.

The road wheels hold grease well as a rule, but should not be left for more than three months. The clutch bearing, which most owners ignore, is in constant motion and takes the thrust of the clutch springs whenever the pedal is depressed Unless it is attended to about every fortnight it will wear loose and spoil the charm of driving by its noise. To sum up, to wait for a squeak is not necessarily dangerous, but it is expensive, as the car s life, and consequently its second hand value, may be greatly reduced.

### *Distinguishing Badges for Doctor's Cars*

The question whether doctors' cars should be distinguished by some kind of badge has recently been discussed in the motoring press. It is argued that ambulances and fire-engines are privileged in traffic, and that doctors are engaged on equally urgent duties. Moreover a doctor's car often has to be left at some distance from an official car park Again, those standing by victims of wayside accidents should be able to recognise a doctor and summon him to assist. It is doubtful whether medical men as a whole would press for such a badge. Even collective advertisement is against the spirit of the profession, and the degree of the elegance or luxury of his car would not be a useful addition to the ways in which the public may assess the skill or success of an unknown doctor The practitioners in any given locality are usually well known to the police, and these, on the rare occasions when the matter is really one of minutes, always seem ready to facilitate the passage of his car through traffic.

## HEALTH OF THE ROYAL AIR FORCE

Nearly all the items of the Report[1] on the Health of the Royal Air Force for 1924 show improvement on those for the previous year, and the Medical Service can congratulate itself on a distinct advance. The only seriously discouraging feature is the increasing number of accidents in flying and for this increase explanations are offered which will be mentioned later The report itself contains elaborate analyses of the data on which it is based, and a series of these documents, even for so small a force, will form a useful record.

During 1924 the average strength was 31,022 men, of whom some 9000 served abroad. The average strength for the three previous years was about 20,000, and compared with these years there were fewer men admitted to hospital fewer invalided, and fewer sick daily The total number of cases of disease and injury was 32 337, which is equivalent to a case ratio of 1010 per 1000 of strength (1227 per 1000 in 1923), but if cases of less than 48 hours duration be excluded the case ratio becomes 404 per 1000 as against 474 in 1923 The number of men daily on the sick list, which was 27 per 1000 in the three previous years, fell to 24 0 in 1924 This figure is for the whole force, but the improvement was seen both in Great Britain (10 5 per 1000) and abroad (37 2 per 1000), the average number of days' sickness per head was also reduced. These last figures illustrate the comparative unhealthiness of foreign stations, and this is further shown by the fact that the death rate abroad was 6 5 per 1000, whilst that at home was only 3 7

### *Accidents and Injuries.*

A regrettable increase in the mortality of the total force—it rose from 3 0 per 1000 in 1923 to 4 5 in 1924—corresponds with a greater number of flying accidents, and these have also helped to bring up the total injury rate from 65 per 1000 in the previous three years to 73 per 1000 in 1924 The number of injuries in the whole Air Force was, in fact, about 2250, excluding heatstroke and the like, and it is surprising to learn that about half of them were injuries to the legs, and that over 30 per cent. were incurred during athletics. There were only five men wounded by hostile gunfire and none of them succumbed; but there were three deaths amongst 22 cases of accidental gunshot wounds.

The percentage of injuries actually resulting from flying accidents on duty—namely, 7 5—seems comparatively small, but it must be remembered that 41 per cent of these—that is to say 60—were fatal, and that they occurred mainly amongst officers. During 1924 31 8 officers in every 1000 were injured whilst flying, and of these 14 4 were killed; whereas for airmen the total injury rate was only 2 per 1000 The number of flying casualties has increased steadily from 80 in 1921 to 100 in 1924, but it is stated that the number of "hours flown" has increased each year even more Aircraft, moreover, are increasing in size and carrying capacity, and consequently a greater number of personnel is exposed to the risk of injury in the event of a crash In 1924 four collisions in the air accounted for 10 deaths, whereas no deaths from accidents of this kind were reported in 1923 It is stated that the number of hours flown per fatal accident was higher in 1924 than in any of the previous years.

### *The Specific Diseases*

For all types of venereal disease the case incidence showed a reduction from 26 2 per 1000 in 1923 to 22 3 in 1924 The number of primary cases—i e, those reporting for treatment for the first time after contracting infection—fell as low as 16 3 per 1000, which decrease was largely accounted for by a fall of 2 1 per 1000 in the rate for primary gonorrhoea. The case incidence abroad remained as high as 30 per 1000, compared with 19 2 at home; but the steady general improvement in the last four years shows that the measures (including prophylaxis) described in the report for 1921 are having their effect, whilst the contrast with the naval figures—the number of fresh venereal infections in the Royal Navy[2] in 1922 ("Total Force") was 83 per 1000—is very remarkable Of upper respiratory infections there was in 1924 a general increase everywhere except in Iraq The Mediterranean littoral is the most unhealthy area from this point of view, and India is the healthiest. Influenza accounted for over 1000 cases throughout the Air Force, but there were no deaths from this cause Pulmonary tuberculosis affected 42 persons, four of whom died.

Interesting figures are shown of disease and injury amongst men of different ages and trade groups, from which it appears that the highest disability rate—from sickness and injuries—is found amongst boys, and that the lowest sickness incidence is found amongst aircraft hands. The age group in which disease is most rife is 24–25 years, and for these ages the number of primary cases of venereal disease is 43 per 1000 The healthiest group is of men from 21–22 years

### *Unhealthy Foreign Stations*

As has been remarked, the foreign stations account for a high percentage of disability The disease rates abroad were 72 per cent. and the injury rates 22 per cent in excess of those for the home forces, and at Basrah, in Iraq, the most unhealthy of the stations, there was amongst the strength of 570 a disease incidence of over 108 per cent., apart from cases lasting under 48 hours; 74 per cent. of these were accounted for by sandfly fever, dysentery, and malaria. Throughout the Air Force abroad the incidence of malaria was 118 per 1000, which was a slight increase, but there was a distinct reduction in the number of primary cases. A steady annual reduction in sandfly fever has also occurred, probably on account of prophylactic measures suggested in the report for 1922. Amongst the features of the account of the forces abroad is the record of an outbreak of 40 cases of bilharziasis at Hinaidi, the largest station in Iraq, where some 2000 men are stationed.

[1] Report on the Health of the Royal Air Force for the Year 1924. London H.M Stationery Office 1 p. 84. 4s.

[2] The Lancet, 1925 ii., 987

The report concludes with a description of the procedure [3] in examining recruits for flying and of the results obtained both then and at the annual re-examinations for officers and airman pilots. A short account is also given of the attempts being made to improve accommodation and sanitation. That such attempts are on the whole successful is evident from the envious remarks often made by other members of H.M. Forces abroad about the quarters enjoyed by the Air Force.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Medical Registration in the Irish Free State.*

IT is stated that the Government of the Irish Free State is about to introduce a Bill for the purpose of prolonging the present system of medical registration by six months from next February, and of empowering the Executive Council to carry it on for a further period of three months, if this be deemed necessary. It is hoped that within the time thus allowed it may be possible to devise a satisfactory system to replace the present one. It is known that the Government and representatives of the medical profession have been in conference on several occasions, and it is hoped that a scheme satisfactory both to the Government and to the profession may be devised.

### *County Medical Officers of Health.*

The Department of Local Government and Public Health has issued to the various county councils a circular on the appointment of county medical officers of health. Attention is drawn to the provisions of Section 21(1) of the Local Government Act, 1925, which lay down that "the council of every county shall appoint, with the approval of the Minister, for every county health district in such county a medical practitioner duly qualified as such and with such other qualifications as may be prescribed, to be the superintendent medical officer of health of such county health district, and such officer shall be known as the county medical officer of health, with the distinguishing name of such county health district." The Minister is satisfied that the success of the new system of public health administration will largely depend on the proficiency of the persons chosen to fill the position of county medical officer of health. The possession of the Diploma of Public Health or equivalent degree will be an essential qualification, and should be supplemented by practical experience. The Rockefeller Foundation has generously undertaken the training of three medical men in public health work. Furthermore, it is recognised that the position of the existing tuberculosis officers possessing the D.P.H. is entitled to special consideration, and arrangements have accordingly been made with the Society of Medical Officers of Health to enable such officers seeking appointment as county medical officers to acquire further administrative experience and a more intimate knowledge of the manifold activities of public health work. These measures are calculated to ensure for the senior positions of the health service of the county a supply of highly qualified competitors. In the circumstances the Minister has decided that, as a condition precedent to his approval, the principle of a selection committee, which has already been found satisfactory in connexion with dispensary posts, shall apply to all appointments as county medical officers of health. A Bill will shortly be introduced to regulate the future procedure concerning appointments of officers of local authorities. The work in some of the smaller counties will not be such as to afford whole-time employment, and in these cases recourse will be had to a joint appointment with a neighbouring county, accompanied by equitable adjustment of the cost. On the other hand, in a county of extensive area it will rest with the county council to consider the question of subdivision. The Minister does not expect that any appointments can be made before April 1st, and he will communicate further with the county councils as to the steps they should take.

### *Irish Medical Committee.*

Several grievances from which Irish medical men suffer were discussed at a recent meeting of the Irish Medical Committee. For some time past Poor-law medical officers who act as registrars of births, deaths, and marriages have been discontented with the remuneration given for their services. Recently attempts have been made to increase their clerical duties, while some of their sources of emolument have been taken from them. Their fees have remained unchanged since the introduction of the system of registration, and are much less than the fees paid in England. The discontent is so great that it is not unlikely that many registrars will resign their posts unless the Government make some attempt to satisfy their demands. If the medical registrars resign, the system of registration will suffer much in efficiency. The Post Office authorities have recently notified the medical attendants on their postal staffs that a lower capitation rate will in future be paid to post office medical attendants who are attendants to the Civic Guards than to those who do not hold both appointments. There is no justification for this lowering of a scale already poor. The Irish Medical Committee also expressed dissatisfaction with the remuneration paid to medical inspectors on the staff of the Department of Local Government and Public Health. The best paid of these gentlemen are paid on the same scale as their predecessors of 70 years ago. On the other hand, in some recent appointments the scale has been lowered, and inspectors have been appointed at a salary of £500 a year with *second*-class travelling expenses.

### *A Board of Health in Difficulties.*

The County Galway Board of Health seems to have involved itself in deep financial difficulties. It is found that its income for the current financial year will fall short of its expenditure by some £12,000 or £15,000. In these circumstances the Board has simply made a request to its various officers and employees that they should consent to a diminution of 10 per cent. in their salaries for the next three months. It is suggested that unless they agree to this demand they are likely to get nothing at all. It is hardly to be believed that the Department of Local Government and Public Health will permit the health authority of the largest administrative area in the Free State to evade its liabilities by an appeal to the charity of its employees. That the Board has been allowed to go so far in its mismanagement is evidence of a lack of proper supervision by the Department. The only way out at the moment appears to be the suspension of the Board of Health and the appointment of a commissioner to administer its affairs.

## BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

### *Alcohol and Tuberculosis.*

SINCE America introduced the "dry" law the statistical data on the occurrence of tuberculosis in conjunction with alcoholism have been the subject of lively study in several European countries, and particularly in Hungary. Prof. Dr. Julius Donath, whose name is well known abroad from his studies on the rôle of cholin in the causation of epilepsy, has just published the results of his researches. He proves by facts and figures that the effects of cleanliness, good nourishment, fresh air, and sunshine in the treatment of tuberculosis can all be counterbalanced by the action of alcohol. He refers to the observation of Martin, that although the Chinese are continually sinning against the rules of hygiene, and their food is mostly unwholesome owing to their poverty, nevertheless tuberculosis is incomparably less frequent in China than amongst European people. The only weapon of the Chinese against the disease is sunshine (which they have in abundance), and their comparative freedom may be attributed in the first place to their modest consumption of alcohol. According to Donath, the object-lesson of the intemperate use of alcohol has been taken to heart by few countries, a notable exception being Finland, which prohibited alcohol as soon as it became independent. Two other Scandinavian countries, Iceland and Norway, have been prevented from enforcing prohibition by reason of economic causes. Their main article of export, fish, is purchased by their greatest customers, Spain and Portugal, only under the condition that they allow heavy wines from those countries to be imported into their lands. The only important State where the effects of dryness can be properly studied is the United States of America. Here it can be shown with most reliable figures that the tuberculosis mortality decreased between 1914 and 1923 by more than 100 per cent. The huge sums which were previously spent on alcohol in the U S.A. (about two milliards dollars yearly) are spent now in improving the conditions of living. Hungary provides a contrast to such blessed conditions. The mortality from tuberculosis is ever on the increase, and there has been a rise from 2050 deaths from the disease in 1921 to 3203 in 1924. It is interesting to note that according to the official statistics tuberculosis mortality in the Jewish population of the country was 21 3 per 1000, in Protestants 38 5, and in Catholics 55 1. Dr. Donath's report has made a deep impression upon the Hungarian Government, and in well-informed circles it is taken for granted that a Bill will shortly be introduced that will greatly restrict the consumption of alcohol, by prohibiting the sale of liquors in certain hours of the day, and by raising the tax, which will incidentally provide means to support public welfare institutions.

[3] THE LANCET, 1925, ii., 748.

### *The Problem of "Es."*

Dr. George Groedeck, the eminent psycho-analyst, gave an address in the Circle of Lawyers on the treatment of bodily and mental diseases. He said that psycho-analysis cannot, by any means, be applied in lieu of the methods hitherto used; it may be resorted to only in cases where these methods are of no avail Such cases are those in which there is a tendency in the organism of the patient towards a certain disease; the patient directly wants the disease, he wants to pose as the centre of events. Other cases are those in which the patient desires to atone for something, and therefore feels a certain velleity towards a certain disease. An example of this was the woman who wanted to kill a man, but on encountering him, when she ought to have acted, slipped on the pavement, fell, and broke her arm, which she wanted to raise against another human being. This was not caused solely by the wish for atonement, but something else also was accountable for it—namely, the moral feeling which was still present in the woman, and which wanted to prevent her committing the crime In both cases the motive power is something incomprehensible and indefinable, which takes root in the extreme depth of the human being, of the human organism—what Nietsche calls *Es* This is not the conscious Ego, nor the Freudian subconscious, but rather something metaphysical, that cannot be denoted by any other term than that of Nietsche. This *Es* is responsible for those situations in which medical science stands impotent; in which everything done for the patient proves vain because *Es* moves towards the disease. The task of psycho-analysis is to direct the attention of the patient to the intention of the *Es*, and to deflect it in another direction. It may happen, said Dr. Groedeck, that psycho-analysis will be swept away by the future and that we and our method will be entirely forgotten; but this cannot disturb us, because we are living in the present. We are surveying this difficult problem from this point of view, and we are trying to solve it.

### *Imminent Strike among the Junior Dressers of the University Clinic.*

The critical economic position of Hungary is being felt in the universities. Whilst in pre-war times sacrifices for the advancement of science knew no limits, and the Budapest University was one of the first to adopt all new appliances regardless of cost, the situation at present is such that only the most necessary outlays are approved by the Ministry. Economy is the principle in every line, and unfortunately it is very detrimental to the training of medical students. The last Order of the Ministry of Public Instruction related to a reduction of the number of junior dressers in the university clinics. Out of about 300 dressers only 25 had some nominal salary, and these were all older dressers, who had acquired their medical diploma several years ago and had served in this capacity for more than three years. The Minister wanted to dismiss nine of them in order to alleviate the budget of the universities. As the professors of the affected clinics objected that this would endanger the successful teaching of the students, a conflict arose which went so far that it was feared that the rest of junior dressers—about 300—would declare solidarity with the dismissed ones, in which case the teaching would have suffered a great deal. This Order to the dismissed dressers was most offensive, for the Ministerial Order wanted them to continue working without any salary. If they accepted it, this would mean their degradation, because having a salary gave a certain distinction to the advanced dressers. The medical staff of the university clinics—professors, adjuncts, assistants, practicants, and dressers—held a meeting at which, after several fiery speeches and hot remarks, the professors succeeded in persuading the younger clinicians to refrain from overhasty steps, because there was hope that the Minister would retain the paid dressers in their position if he heard about the meeting and the atmosphere which ruled there. Direct negotiations were then opened between the Premier himself, Count Bethlen, and Count Klebelsberg, Minister of Public Instruction, and eventually the Order was withdrawn Thus 130 million crowns—about £520—saved the Budapest University from an academic disaster.

### *Tutocaine in Ophthalmology.*

The second ophthalmological clinic of the Budapest University has applied tutocaine in 250 cases. The results, as recorded by Prof. Hoor, the director of the clinic, are not very satisfactory. A report, published in the *Orvosi Hetilap*, No 36, 1925, supports the view that tutocaine cannot compete with cocaine as an ophthalmological anæsthetic. Neither is it superior to holocaine; on the contrary, in the deeper parts of the eye tutocaine failed to produce anæsthesia, whereas cocaine and holocaine had acted promptly. It can be recommended, however, to produce anæsthesia in cases of operations performed in the superficial layers of the cornea and conjunctiva. When injected, its irritant effect on the tissues is greater than that of novocaine, while it does not render the field so bloodless. Its only advantage over novocaine is that its anæsthetising power is of longer duration; on the other hand, it may compete with it from the point of view of cost, because, according to some authors, half the quantity of tutocaine suffices to attain the same effect as produced by novocaine.

### *Compulsory Notification of Malaria.*

The Minister of Public Welfare has issued an Order enacting the compulsory notification of malaria in towns and cities to the chief medical officer, and in the country to the district physician. The Minister was induced to do so on account of the great number of cases of malaria occurring at some parts of Hungary, showing a decided epidemic character. If notifications are made on a wider scale the Minister will make provisions for the enlightenment of the rural population through popular lectures and instructive films.

## SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

### *Cape Town and Venereal Disease.*

CAPE TOWN appears to have taken a retrograde step in regard to the treatment of venereal disease. A good deal of pioneer work in this respect has been done by the South African branch of the National Council for Combating Venereal Disease, now to be known as the South African Society for Social Hygiene. Under the auspices of its council venereal clinics were established a few years ago in a convenient quarter of the city, and voluntary help was given by medical men and women. Subsequently, the health department of the Cape Town Corporation decided to take over the work and appoint their own medical officers. This they did, retaining some of the voluntary workers on their paid staff. A few months ago the health committee of the city council, against the advice of Dr. Shadick Higgins, their medical officer of health, and in defiance of the wishes of a representative deputation, decided to close the original clinic and dispense with the services of the two medical women who had successfully conducted the tri-weekly clinics for women for the past four years. The reason given for this move was that of economy, and it was urged that a clinic at the City Hospital would meet the needs of both men and women and save the fees now given to part-time medical officers. It remains to be seen whether the attendance of patients under these new conditions will maintain their average of the past few years.

### *Self-Government in a Leper Institution.*

A leper institution in the Transkei, S.E. Cape Colony, has of late years been the scene of an interesting experiment in administration. The institution is practically governed by the lepers themselves. Five headmen are elected from amongst the patients and these are responsible for the discipline of the whole. Any patient breaking the rules is tried by these headmen in the presence of their fellows and the punishment, if any, is determined by the headmen and patients in council. There is a right of appeal to the superintendent and, through him, to the Union Government, but this is practically never exercised. Admirable results have followed the introduction of what in schools would be called the prefect system. Under the old system of control 40 native guards serving under six European officers were kept constantly employed, and a man-proof fence enclosed the whole leper location. Under the new régime the guard has been reduced to 18 natives, of whom half are patients, and two European officers. The man-proof fence has been replaced by one of the usual sort, and beyond a roll call every morning and evening no methods are taken to prevent escapes. This enlightened system of control has now been in force for four years and owes its inception to the superintendent, Mr. J. W. Macdonald, who laboured hard for improving the comfort and happiness of the lepers. The statistics of escapes before and after his arrival testify to his success. Previous to 1922 as many as 60 lepers would attempt escape during the year. Since that year the highest number reached is six and the lowest three. The institution is, moreover, run on lines of sound economy. Large farming operations are undertaken, and all butter, milk, meat, and vegetables required for the patients and staff are supplied locally. Trees are also grown for firewood. Most of the work is done by the more able-bodied amongst the lepers and these are paid for their labour. The money thus earned is sent home to their relations and forms a link between the sufferer and his friends, which is much valued by both. A shop on the premises provides the lepers with any little luxury at cost price. Schools and creches are provided for the younger inmates.

### *Visit of the Medical Secretary of the B.M.A.*

Dr. Alfred Cox, medical secretary of the British Medical Association, is at present on a visit to South Africa. Dr. Cox's ten days on the Rand were occupied in visiting the Rand hospitals, the medical school, the South African Institute of Medical Research, the Miners' Phthisis Bureau, and the Witwatersrand Native Labour Association Hospital. He was entertained to lunch on Nov. 25th, at the Scientific and Technical Club, Johannesburg, by the Witwatersrand branch of the B.M.A., and he was present at the annual dinner of the branch held on Nov. 26th at the Carlton Hotel, Johannesburg. At this dinner about 100 members and guests were present, and the chair was occupied by Sir Spencer Lister. Sir Julius Jeppe proposed the toast of the British Medical Association. In reply, Dr. Cox said that he hoped to see London made the centre of post-graduate work in the Empire. The B.M.A., he said, had been formed on the model of the British constitution. They were a collection of families of medical men scattered over the Empire. In England, as the parent body, they were called to help the other branches. But they never interfered with them. They laid great stress on the fundamental maxim that the patient came first.

### *Bloemfontein Hospital Board.*

At the monthly meeting of the Bloemfontein Hospital Board held on Nov. 24th, under the presidency of the Rev. F. P. Roth, strong opposition was voiced to a recommendation from the medical committee advising that patients should either be free patients or should pay a minimum of 10*s.* a week. The committee held that those patients paying 7*s.* 6*d.* a week should either be made to pay the full 10*s.* or be made free patients. Several members of the board took exception to this recommendation of the medical committee on the grounds that it was unfair to label as paupers those who could only afford to pay less than 10*s.* Dr. van Rippen, speaking as a medical man, said that to his knowledge many who did not at present pay 10*s.* a week to the hospital could well afford to do so. The recommendation was not accepted.

### *Training in Mother-Craft.*

To Cape Town belongs the distinction of having the first mother-craft training centre in South Africa. This has been recently started through the untiring efforts of the Child Welfare Protection Society, which is the Cape Colony branch of the National Council of Child Welfare. A wing of the Society's home for infants and young children, known as the Lady Buxton Home, has been adapted for teaching purposes and a newly added hostel provides accommodation for the students. These include (1) trained nurses who take a four-months' course in infant dietetics; (2) midwives who remain for six months; (3) untrained students who wish to qualify for the position of domestic nurses. Their period of training lasts one year, and includes the care and management of infants from birth up to the age of 6 years.

HOSPITAL ACCOMMODATION AT SWINDON.—There has long been a serious hospital problem at Swindon, the headquarters of the Great Western Railway works, with a population of some 90,000. The Great Western Hospital of 15 beds was established by the railway company to meet the needs of their employees, but their wives and children have to make use of the Victoria Hospital, which has 25 beds and seven cots. The combined accommodation is entirely inadequate, and proposals have been made for the enlargement of one or other of these institutions. Two years ago Mr. Roden Orde recommended the establishment of one hospital for the whole population with from 150 to 200 beds. The Swindon Town Council has just appointed a committee to consider the possibility of establishing such a hospital, and its cost.

# SEXUAL OFFENCES AGAINST YOUNG PERSONS.

## REPORT OF THE HOME OFFICE COMMITTEE.

THE Report of the Departmental Committee on Sexual Offences against Young Persons sets out fully the conclusions reached by the Committee after considering the evidence of some 75 witnesses, including judges, magistrates, barristers, chief constables, medical officers, police surgeons, and representatives of the Church of England, the Home Office, Board of Education, local authorities, the Six-Point Group, and other bodies. The recommendations of the Committee are summarised in Section IX. of the report as follows:—

### FORTY-THREE RECOMMENDATIONS.

1. That the annual criminal statistics should contain a separate table giving complete returns as to sexual offences which are against young persons, and that the statistics for "attempts" should be shown separately from those for the full offence.

2. That it should be made an offence, triable summarily and governed by the law as to indecent assaults, for a male person to commit an act of gross indecency with a young person, male or female, under 16; that the young person shall not be prosecuted for being concerned in the offence.

3. That courts of summary jurisdiction shall have power to grant a separation, maintenance, costs, and the legal custody of her children, to a wife whose husband has been convicted of incest, carnal knowledge, or of the attempt, or of a grave indecent assault, upon one of his daughters.

### *The Age of Consent.*

4. That the age of consent shall be raised to 17, with amendments to the law consequent thereon.

5. That the defence of reasonable belief that a girl was 16 or over shall be abolished; that where there are extenuating circumstances a young man found guilty on indictment and placed on probation, shall not have a conviction registered against him.

6. That 12 months shall be the time limit for taking proceedings under the Criminal Law Amendment Act, 1885, Section 5 (1)

7. That the jurisdiction of petty sessions shall be extended to try, where the accused consents, offences of gross indecency; and of attempts to have carnal knowledge of a girl under 13, or under 16; and of attempted incest with a girl under 16. That power be given the justices to imprison up to 12 months for attempted carnal knowledge and for attempted incest.

8. That quarter sessions shall have power to try all sexual offences against young persons, provided that the Court is presided over by a recorder, or by a chairman or deputy having professional legal experience.

9. That in indecent offences properly trained women shall take the statement of girls; but where this is not possible, that a woman shall be present while the policeman is taking the statement

### *Examination by a Medical Woman.*

10. That where a medical examination of a girl is necessary it should, whenever possible, be carried out by a woman doctor.

11. That where proceedings are instituted by summons, such summons shall be made returnable early.

12. That chief constables shall be asked to consult the Director of Public Prosecutions in cases of defilement of girls under 13, and of indecent offences upon a number of children, and of offences in which disease has been communicated to children or young persons.

13. That in all except the simplest cases a solicitor shall be engaged to assist the prosecution in sexual offences against young persons.

14. That separate waiting rooms for young persons shall be provided by all courts.

15. That magistrates shall, whenever possible, take all cases of sexual offences against young persons at a fixed time convenient to the child and its guardian; and that in petty sessional courts with short lists these cases shall be taken first, or after the short cases have been disposed of That where the evidence of a young person is necessary and available, a remand shall not be granted till his or her evidence has been taken.

16. That courts of assize and of quarter sessions shall take these cases first, whenever possible, after the pleas of "Guilty" or after the emergency cases have been disposed of.

17. That courts should be reminded of the power to dispense with the attendance of young persons under Section 31 of the Children Act, where their evidence is not required.

18. That young persons shall not be required to attend before the grand jury, provided that the bill shall not be ignored without hearing the evidence of the young person.

### *Procedure in Court.*

19. That attention shall be paid to the position of the young witness in court, so as to lessen the distance the voice has to carry, and so that he or she shall not be face to face with the accused at close quarters.

20. That a suitable woman shall always be present in court to the knowledge of the girl witness. That a matron shall be available to take charge of young witnesses while waiting to give evidence.

21. That wherever a woman is entitled to sit as a magistrate, she should be asked to attend on the bench when girls are concerned in a case of indecency.

22. That, subject to certain reservations made, the court shall be cleared when young persons are giving evidence as to an indecent offence, and that at no time shall a young person under 16 remain in court, unless his or her presence is specifically required.

23. That, wherever justifiable, the evidence of a child who can tell a connected story shall be taken upon oath.

24. That those initiating or conducting prosecutions should bear in mind that in view of the decision of the Court of Criminal Appeal in R. v. Crocker, the absence of corroboration is not a bar to the securing of a conviction.

25. That the extreme difficulty of bringing to justice an offender committing offences against a number of children separately, shall be rectified by Parliament.

26. That neither the name, address, nor photograph of a young person concerned as a witness, or as a young offender, in these cases shall be published, except by the express authority of the court.

27. That the words "from birth or an early age" and "from an early age" shall be deleted from Section 1 (c) and 1 (d) respectively, in the Mental Deficiency Act, 1913.

### *Mental Report before Sentence.*

28. That after conviction, but before sentence, the bench shall remand, for a mental examination and report, all cases of indecent exposure, all sexual offenders previously found guilty of an indecent offence, and all cases in which the court suspects mental disease, disorder, or defect.

29. That all courts shall make arrangements for the services of a mental expert to be at their disposal.

30 That those who commit repeated indecent offences against young persons should be subject to prolonged detention in suitable institutions.

31. That the penalties imposed for sexual offences against young persons should be adequate to the circumstances of the case.

32. That legal aid, and better facilities for appeal, for offenders tried summarily, should receive consideration.

33. That courts trying sexual offences against young persons shall refer to the petty sessional court the question whether the further protection of the young person is necessary; and that the justices shall take action, if the case requires it, in the interests of the young person or of his or her brothers or sisters.

34. That the words "unlawful carnal knowledge" shall be inserted before the words "seduction or prostitution" in the Criminal Law Amendment Act, 1885, Section 12, and in the Children Act, 1908, Section 58 (1) (g).

### *Amendment of Children Act.*

35. That the Children Act, 1908, shall be amended as follows: (a) First schedule.—Incest to be added as an offence. (b) Section 20.—The police to coöperate with local social workers where it is necessary to remove a child temporarily to a place of safety. (c) Section 21.—Payment from public funds to be available for a young person committed to the care of a "fit person" (under Sections 21, 58 (7), or 60, respectively); the address of the young person so committed to be notified to the court; institutions which represent the "fit person" to be approved, registered, and regularly inspected. Power to be given to take action for the protection of young persons offended against by the man cohabiting with the mother. (d) Section 58 (1) [illegible]— The words "is found wandering and" to be deleted before the words "having no parents." (e) Section 58 [illegible]— Incest, unnatural offences or indecent assault by a father on one of his own children to be a ground for taking [illegible] of protection on behalf of his sons or daughters. (f) Section 58 (1) (g).—Procuring or aiding or abetting by either [illegible] to be a ground for taking action on behalf of [illegible] the children who are in moral danger.

36. That there shall be power to deal with [illegible] who are beyond control as outlined in the [illegible]

*Condition of Special Homes.*

37. That voluntary societies and workers should discriminate more carefully as to the children sent to special homes, and as to older girls sent to rescue homes; that they should receive reports as to progress, and should make arrangements for the return of the child or young person to a more natural environment as soon as possible.

38. That where the child victim of an offence has to be removed from its home, boarding out under proper safeguards shall, where possible, be resorted to; that the age limit for boarding out in the Children Act should be abolished.

39. That children committed to special homes shall only remain until they have recovered, and shall then return to their parents, or be boarded out, or be sent to an ordinary home or industrial school.

40. That where the court makes a probation order conditional on residing in a home, it shall be one which is approved, registered, and inspected; and that the period of training shall not exceed six months without careful review by the court.

41. That the statutory requirements as to the care of children employed in entertainments shall be extended to include the care of young persons up to 17.

42. That there should be better supervision in parks, in fairs, in cinemas, and in school precincts.

43. That student teachers should receive instruction at college as to the best methods of giving older children, individually, instruction on matters of sex.

We comment on another page upon some medical aspects of this many-sided report.

# Public Health Services.

## REPORTS OF MEDICAL OFFICERS OF HEALTH: A BRIEF SURVEY.

THE Ministry of Health has issued the usual circular with regard to these reports for 1925, an exceptional feature being the intimation that a survey report, indicating the measure of progress made during the preceding five years, is required for the year 1925.

We have commented on many of the 1924 reports. The year 1924 was a wet and cold year, and was characterised by a considerable prevalence of influenza in the first quarter, followed later by an increased prevalence of encephalitis lethargica in many districts. The death rates were in consequence not usually so favourable as in 1923, and respiratory diseases were responsible for increasing both the general death-rate and infant mortality. Some districts, however, succeeded in scoring their lowest infant mortality rates on record. Typhoid fever of the usual type was not prevalent, but a number of outbreaks of paratyphoid were reported. Occasionally these were associated with carriers and milk infection, but in many cases they occurred in the early summer, affecting chiefly women and children, and no food cause could be found. Small-pox of a very mild type was endemic in several districts, but the virulent type appeared in a small outbreak at Willesden. The question of immunising for diphtheria has made some progress. It is now used for the staffs of many fever hospitals, and has been applied in the case of Edinburgh to school-children on a large scale. Serum immunisation against measles has also been used in Glasgow.

There appears to be an almost general shortage of hospital accommodation for surgical tuberculosis. As yet the results obtained by the training of tuberculous ex-Service men do not appear to be very satisfactory. Some very high death-rates from cancer were reported, and local cancer investigation committees have been established in several districts. Venereal diseases show a decline, especially in new cases of syphilis, and the better facilities provided at the centres are reflected in the increased number of attendances per case.

As regards maternity and child welfare, it cannot be said that much progress has been made in preventive midwifery, designed to cope with the high materna and neonatal mortalities. Several districts report a difficulty in stopping the practice of "handy women." There are signs of better coöperation between the county councils and the urban districts responsible for maternity and child welfare schemes. Many of the county councils are making strenuous efforts to attain the ideal that no village shall be without its properly qualified nurse-midwife, and for this purpose the services of the voluntary nursing associations are being well utilised. Light treatment is being installed at many of the centres for the use of children of pre-school and school ages. Considerable progress has been made in many districts in the organisation of complete schemes for dealing with crippled children. An advance has also been made towards the unification of the public medical and nursing services.

Among school-children there is much need for more complete dental treatment, and several school medical officers refer to malnutrition in school-children due not to insufficient food but to the wrong kind of food.

The introduction of the regulations for graded milk has certainly given a fillip to the improvement of the milk-supply. The sale of graded milks has made little headway, but, on the other hand, the agricultural committees of many county councils have held clean milk competitions and stirred up an interest in this question by means of lectures and demonstrations. The examination of milk for tubercle bacilli shows that there is no decrease in the frequency of tuberculous udders, and the reintroduction of the Tuberculosis Order is anticipated with satisfaction. Rural districts are beginning to take up the periodical inspection of milch cows.

The housing question is still a great difficulty. Few districts have been able to catch up any arrears, and the majority have been unable to provide for the natural increase of the population. Here and there, however, there was a more optimistic note. The smoke abatement question remains much as it was. The regional area scheme for the Manchester district which aroused some interest has been turned down since.

The need for education of the public in health matters has been urged in many reports, and Blackburn has given a notable lead in this respect. Perhaps the chief gains of the year have been improvements in administration. One example is cooperation between the local authorities and the voluntary hospitals and nursing associations; another is the pooling of hospitals for infectious diseases in county areas. The establishment of the Sheffield Medical Advisory Committee is another good example of coöperation, and we have already mentioned the organisation of schemes for cripples and the unification of the public medical and nursing services.

## SCHOOL MEDICAL SERVICE.

### A SURVEY OF 1924.

THE ever-increasing scope of school medical work in addition to the routine examination of every child at least three times in the course of his school career is becoming one of the prime factors in preventive medicine. Each year sees a closer linking-up with antenatal and child welfare schemes and a more complete coördination of all health activities, both public and voluntary, bringing the medical officer into close touch with the general practitioner and the consultant and making for harmony in the common interest of prevention and of early recognition and treatment of disease. The school has now become the clearing house for incipient diseases.

Not least of the great services rendered by school medical workers is the quickening of interest amongst the lay public in general and personal hygiene. Throughout the country 60 per cent. of the parents attend the medical inspection and greater advantage is being taken each year of the wide facilities provided for advice, help, and treatment. The mental attitude of the public has undergone a complete change;

personal uncleanliness and verminous conditions are now viewed with shame. Advice and practical teaching on personal hygiene, dietetics, clothing, lighting, exercises, &c., together with better general hygiene have already resulted in a widespread general improvement in the physique and bearing of the present-day elementary scholar, while there has been a marked decline in mortality at school and pre-school ages during the past 20 years. The child of yesterday as the mother of to-day is putting into practice the lessons already learned.

The enormous amount of dental caries gives colour to the belief that nature is finding little use for the teeth and is now treating them as foreign bodies. Whatever be the cause or causes of the decay, dental caries is being tackled in Herculean manner by the school dentists and much propaganda is carried on by them in the way of lectures to the parents. The reports of school medical officers leave one in no doubt as to the advisability of removal of septic tonsils and adenoids. Aural surgeons are unanimous in their condemnation of the offending member, but many and varied investigations by S.M.O.'s have traced septic absorption from the throat as at least a large contributory factor in rheumatism, chest and lung complaints, anæmia, malnutrition, general physical and mental debility. Operative treatment is usually in the hands of experienced surgeons and skilled anæsthetists, while the general aim is to keep the child in bed from 24 to 48 hours following operation.

Ionisation as a means of treatment in selected cases of otorrhœa seems to be favoured by an increasing number of aural surgeons, while many ophthalmologists point the need for the very early treatment of squint. Dirt diseases and infections—e.g., impetigo, scabies, blepharitis, and conjunctivitis—all show a decided decrease during 1924, and ringworm of the scalp is a rapidly disappearing disease. Increased inspections by nurses, together with the help and observant coöperation of teachers, are tending to minimise the spread of infections in the schools, and even the control of small-pox epidemics was helped by keeping the schools open and so ensuring better supervision of the children.

Special classes and residential schools are widely provided for the adequate training of defectives, both physical and mental. Open-air classes and schools are held where the batteries of nature are trained on the invasive powers of disease, and it is from such institutions that much of our knowledge is coming—on the best lines of tackling these defects. Since Sir George Newman stated that between 80 and 85 per cent. of all crippling defects could be prevented or cured, many authorities have started orthopædic schemes under the direct supervision of skilled surgeons and with remedial clinics and numerous training centres. The financial economy of these special means of preventing, easing or curing chronic invalidism is strongly shown in many of the school reports. Whether the bombshell of Circular 1371 will disintegrate the rising structure remains to be seen, but if the suggested "economy" falls on the medical work, it will be the most wasteful economy the country could adopt; even the exclusion of the 3- to 5-year olds would remove children at the age when most effective preventive and curative work can be undertaken, and there is, at present, no other means of bringing these children under medical observation in the mass.

The mass of material and the excellent opportunities in the examination of these great numbers of everyday children has resulted in many original observations, and few reports will be read wherein some special work is not recorded. Rheumatism has claimed wide attention, and in Bristol, Birmingham, and London, amongst many other places, useful contributions have been made on the hereditary and environmental factors as well as on early diagnosis and treatment at open-air institutions. Dr. Vincent Coates, working in conjunction with Dr. R. E. Thomas, the deputy S.M.O. of Bath, finds a useful diagnostic sign in the presence of small nodules over the spinous processes of the vertebræ and along the subcutaneous border of the ulna. Encephalitis lethargica, with its 50 per cent. mortality-rate, has called for some careful reports; in Dr. F. C. Shrubsall's (London) series of 103 cases, only 42 had apparently completely recovered, and amongst 57 cases observed by Dr. H. Herd, of Manchester, only 8 could be described as normal.

The complex question of "fitness" has attracted many observers, and Dr. J. G. Woolham, of Manchester, has evolved a series of anatomical measurements and physiological tests which, when applied to a series of boys under medical attention, showed a close positive association with the findings of purely clinical examination by independent medical men. Dr. Percy Scott examined the blood pressure in 1633 boys in London and finds that the commonly accepted rule that blood pressure rises uniformly throughout life is not supported, but that during adolescence, and particularly about the age of 16 or 17, the heart in boys is performing more work in comparison with its weight than at any preceding or subsequent period of life up to 40. He also noted that in schools where a strict discipline is maintained, the average systolic and pulse pressure of the boys are appreciably higher than in the more easy-going schools, the pulse-rate being reduced in compensation. To the healthy boy this is an advantage, but to delicate youths harm is likely to accrue from the keying up of the blood pressure.

Many other subjects of vital importance have been selected for investigation by individual members of the School Medical Service. Enough has been said to give an idea of the useful and progressive work which is being done.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 19TH, 1925.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 180 (previous weeks, 141, 115, and 105); scarlet fever, 1835; diphtheria, 978; enteric fever, 38; pneumonia, 1832 (previous weeks 1917, 1170, and 1531); puerperal fever, 51; cerebro-spinal fever, 8; acute poliomyelitis, 8; acute polio-encephalitis, 2; encephalitis lethargica, 44; continued fever, 1; dysentery, 8; ophthalmia neonatorum, 111. There were no cases of cholera, plague, or typhus notified during the week.

Of the 180 cases of small-pox, 118 were reported from the county of Durham as follows: Gateshead C.B., 8; Blaydon, 51; Chester-le-Street, 5; Consett, 1; Durham, 1; Jarrow, 1; Ryton, 3; Whickham, 1; Chester-le-Street R.D., 7; Easington R.D., 21; Houghton-le-Spring, 8; Lanchester, 4; Sunderland, 7; and 14 from the West Riding of Yorkshire—namely, Rotherham C.B., 1; Rawmarsh, 13.

*Deaths.*—In the aggregate of great towns, including London, there was 1 death only from enteric fever, none from small-pox, 78 from measles, 10 from scarlet fever, 48 from whooping-cough, 30 from diphtheria, and 132 (previous weeks 110, 100, 73, and 61) from influenza. In London itself there were 31 deaths from measles, 7 from diphtheria, and 26 from influenza.

# The Services.

## ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lt. H. M. Willoughby to be Surg. Sub-Lt.

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. R. N. Hunt, half pay list, late R.A.M.C., retires on account of ill-health.

### ARMY RESERVE OF OFFICERS.

Lt.-Col. F. E. Bissell, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

## ROYAL AIR FORCE.

Flight Lt. G. Kinneir is transferred to the Reserve, Class D.2.

### RESERVE OF AIR FORCE OFFICERS.

P. A. Carrie is granted a commission in Class D.D. as a Flying Officer.

# Correspondence.

"Audi alteram partem."

## GLYCOSURIA AND LIFE ASSURANCE.

*To the Editor of* THE LANCET.

SIR,—May I be allowed a comment on Dr. Knyvett Gordon's letter in your issue of Dec. 19th last. The data in the letter are rather scanty, as neither the exact composition of the meal nor the time elapsing between it and the blood-sugar estimation is stated. Assuming, however, that the case really is one of a low renal threshold—i.e., one of glycosuria without hyperglycæmia — the proposer's remedy is simple: he should propose for a policy with another company. Although previous rejection would lead to a very careful scrutiny of all the facts by the second company it would by no means prevent his acceptance at ordinary rates if the circumstances satisfied the assessors that he was a normal risk. It happens quite frequently that a proposer is thus accepted by another company. Without going so far as Dr. Gordon in regarding a case of renal glycosuria as a " better risk in regard to carbohydrate metabolism than a normal man," I may say that I have recommended many such cases for acceptance if satisfactory in all other respects.

I am, Sir, yours faithfully,

OTTO MAY, M.D., &c.

Dec. 24th, 1925. President, Assurance Medical Society.

⁂ Dr. Knyvett Gordon's letter was published because it is well that instances which point towards arbitrary treatment in such matters should be ventilated. The case to which he alludes was recognised immediately by the company whose methods were criticised, and the following explanation has been sent to us :—

"When this proposer attended for examination he was examined by one of our own medical directors, and although Dr. Gordon says that he was 'a healthy man, of wiry physique, with clear family and personal history,' he was, in our examiner's opinion, not robust-looking—his weight was very light, he looked older than his age, and he was slightly emphysematous. Dr. Gordon says that the urine was 'boiled with a blue solution and the rest of the specimen poured down the sink'; whereas, when the urine was found to reduce Fehling's solution, the rest of the specimen was sent to one of the leading London laboratories and was tested both by Fehling's and Benedict's solution, and we also had a phenylhydrazin test made. The substance was shown to be glucose, and the quantity was 1·88 gr. per ounce. As a result of this we did not, as Dr. Gordon says, 'totally reject him,' but postponed the case for six months, and recommended the proposer to place himself in the hands of his medical adviser."

We need not enter into further details of the case, but it would seem that no careful insurance officer could have acted more justly in relation to other policyholders and with more consideration to the proposer himself.—ED. L.

## IMPETIGO CONTAGIOSA.

*To the Editor of* THE LANCET.

SIR,—In connexion with Dr. Haldin-Davis's admirable article on the treatment of impetigo contagiosa in your issue of Dec. 19th there are a few points concerning the ætiology, course, and prophylaxis of the disease which are not, as a rule, sufficiently emphasised.

In the first place, I am convinced that it is impossible to abort an attack by local measures alone, and that, once the eruption is well established, recovery is not so much due to the local treatment we employ, however carefully and thoroughly it may be applied, but to the gradual development of immunity to the infecting streptococcus and perhaps, to a less extent, to secondarily invading staphylococci. In other words, although by our local antiseptic applications we may check the spread of the eruption and hasten its disappearance, the patient cures himself by antibody production, and I believe that most cases, if left untreated, would run a definite course lasting from two to six weeks.

During the war I developed a very severe attack when on a hospital ship in the Persian Gulf during the hottest part of the year. I treated myself assiduously for some weeks with all the resources of the ship's dispensary, but entirely failed to check the outbreak of fresh lesions. Within 48 hours of landing in the relatively cool atmosphere of Bombay, however, new lesions ceased to appear and, apart from a few dried crusts, I was well at the end of a week. Rarely, too, one meets with cases in which the disease lasts not weeks but months, in spite of the most rigorous local treatment. One case I remember well—a little girl of some 3 years of age—in which the eruption, which was of the bullous type, had been present for over two years; a long-chained streptococcus was repeatedly recovered from the early lesions and the same organism was found in almost pure culture in the nasal and buccal mucous membranes, and in fæcal cultures it predominated over the *B. coli*. An autogenous vaccine produced febrile reactions but led to some improvement. It was decided to give a polyvalent antistreptococcal serum, but the mother removed the child from hospital and I lost sight of her. Another case was that of a young man with bullous impetigo of the face, neck, and hands in whom the disease lasted at least six months; he improved with an autogenous vaccine, and eventually the eruption cleared rapidly after two injections of antistreptococcal serum. He had had thorough local treatment at two other clinics before he came under my care.

Recently I treated a patient with severe impetigo of the face, neck, and scalp, in whom the disease ran a course of about four weeks, without, I think, being much influenced by local applications. At the end of his attack his wife came to me with three or four early lesions and she complained of feeling very seedy. I thought it worth while to try to abort the attack, and she was given a dose of a mixed vaccine of streptococci and staphylococci cultured from another case of impetigo. The result was dramatic, as on the following day the lesions had dried up, she felt infinitely better, and there was no further development.

Impetigo contagiosa is not always, as many textbooks would suggest, a trivial disease. In children and in adults of both sexes it may be the starting-point of obstinately recurring streptococcal fissures and intertrigo and of secondary staphylococcal lesions, such as boils; in men, of course, as Dr. Haldin-Davis points out, the risk of coccogenic sycosis becoming superimposed on a neglected impetigo is a very real one. The prognosis depends partly, no doubt, on the thoroughness with which the local treatment is carried out, but to a greater extent, in my opinion, on the rapidity and degree of antibody production. For this reason it is advisable to insist on the patient resting completely during the active stage, and he should, if possible, lie up out of doors; when the attack is subsiding, a fortnight's holiday in a cool, bracing place will complete the cure, and reduce the chances of secondary complications to a minimum.

Lastly, one meets with cases, most commonly in hospital clinics but also in private practice, in which there would appear to be a generalised streptococcal infection both of the skin and mucous membranes. The patients are usually children in the first decade. On the skin are found impetiginous lesions, fissures at the muco-cutaneous junctions, intertrigo of the natural folds, and perionychia. There is a diffuse catarrh of the mucous membranes, stomatitis, rhinitis, nasopharyngitis with adenoidal and tonsillar hypertrophy, bronchitis, and "mucous colitis." A large proportion of these children have thread-worms, and, as a result of scratching, streptococcal infection of the perianal and vulval regions takes place. The underlying condition corresponds to that described by the late Dr. Eustace Smith as "mucous disease." The chief causative factors are an excessive carbohydrate dietary and unhealthy surroundings. Local treatment alone is useless. The main indications are to keep the child as far as possible in fresh air and abundant sunlight (in winter artificial light baths are invaluable), to exclude soft starchy food and sweets rigidly from the diet, which should consist mainly of fresh meat, fish, eggs, green vegetables, fruit, milk, crisp toasted wholemeal bread-and-butter, and, for a while, to give rhubarb s a laxative and an alkaline bitter mixture before meals. Under this treatment the mucous membranes ry up, and the streptococcal infection of the skin radually disappears.

I am, Sir, yours faithfully,
H. W. BARBER.

Devonshire-place, W., Dec. 28th, 1925.

## INSULIN AND THE OPTICAL ACTIVITY OF URINE.

*To the Editor of* THE LANCET.

SIR,—Former observations have taught us that insulin causes transitory glycosuria in normally fed rabbits and in healthy people if its experimental application is suddenly stopped. This "paradoxical glycosuria" may become evident either at once or some time after the last application of insulin; it may persist for one or more days, and it may reach 1 per cent. and more. These experiments further have shown that it makes no difference if the insulin be injected or given by mouth. The insulin A.B. brand, insulin Tetewop, and insulin Fornet prove equally effective.

In the following experiments polarimetric examination of the urine showed the presence of optically active substances besides the glucose.

A rabbit of 2 3 kg., the urine of which had always been free from glucose and albumin, was injected with 0 units insulin A.B. brand. Six hours later the urine caused a deviation of the polarised light to the left of 2·5°. This polarisation to the left persisted for three days and varied from 0·05° to 0·4°. On the fourth day the polarimetric control of the urine showed a rotation of 0·3° to the right, after which the urine became normal again. Repeated experiments gave similar results.

A healthy man, 33 years, received on three successive days altogether 82 units insulin Tetewop in the form of pills made up with dried ox bile and powdered liquorice root. From the second day onwards the formerly absolutely normal urine began to influence the polarised light and caused a rotation that varied on the different days from 0·4° to the left to 0·6° to the right.

Another healthy individual also received insulin internally, with the difference, however, that the pills were not made up with Dutch insulin, but with insulin Fornet. Within four days 72 units were given, and the result was again that from the second day onwards the urine began to deviate the polarised light to the left (0·3°). On the fifth day the rotation reached 0 5° to the left and changed then on the seventh day into a rotation of 0·1° to the right.

These experiments and similar ones with identical results prove that the healthy and normal organism, on the experimental application of insulin, reacts by discharging in the urine an optically active substance that turns polarised light to the left. These observations suggested the idea that diabetic persons might react in the same way when treated with insulin.

Mrs. M. B., 56 years, 85 kg., middle case of diabetes; no glycosuria on a diet with no carbohydrates and 50 g. albumin. Twice a day injections, each of 20 units insulin A.B. brand; 50 g. of carbohydrate, and 75 g. albumin. From the second day onwards the urine turned polarised light to the left, varying from 0 5° to 1 5°. After reduction of the quantity of insulin to 10 units the urine became again optically inactive.

Mr. R. L., 33 years, 81 kg., slight case of diabetes, tolerance 40 g. carbohydrates. No glycosuria with three insulin pills Fornet, concentration III., three times a day; 100 g. carbohydrate, and 60 g. albumin. Towards the end of the first week the urine showed rotation of the polarised light to the left (1°). After reduction of the insulin doses to three pills concentration II. three times daily this symptom disappeared again.

These experiments and other similar ones show that not only the normal, but also the diabetic organism, when treated with an excess of insulin, discharges into the urine substances that turn the polarised light to the left. The origin and nature of these substances is to be discussed later. We want to draw attention to a hitherto unknown symptom that seems to indicate an overdosage of insulin and that might become useful for the routine control of diabetics under insulin treatment.

We are, Sir, yours faithfully,
F. W. FORNET,
E. CHRISTIENSEN.

Institute of Microbiology, Saarbruecken, Dec. 22nd, 1925.

## FATIGUE AND INFECTION.

*To the Editor of* THE LANCET.

SIR,—Perhaps you will allow me to make a few comments on your leading article of Dec. 19th in relation to its bearing on the problem of influenza. The work of the late Dr. Spaeth and his collaborators has always interested me since it was first announced in 1922, because I thought, and still think, that it may have some bearing on the explanation of the pains and aches associated with a typical attack of influenza.

In an article which appeared six years ago,[1] I drew attention to some rather curious phenomena associated with an attack of influenza. This was elaborated in my M.D. thesis of 1920, published later.[2] I make this little historical note because in your leading article of July 22nd, 1922, on the Ætiology of Influenza, you state in regard to the investigations of Prof. J. McIntosh:

> "A survey of all the facts at his disposal led the author of the report to the conclusion that the essential changes in influenza are due to the toxins of Pfeiffer's bacillus, which it produces whilst superficially placed in the respiratory passages, invasion of the tissues being no essential part of the disease."

In my article in the *Glasgow Medical Journal* I stated:

> "It is suggested that a possible explanation of the main distinction between these two states is that the 'primary' is the stage where infection is external to the tissues of the body, being confined to the respiratory and possibly alimentary tracts, with little or no toxic absorption, and that the 'secondary' stage is the stage of toxæmia, possibly accompanied by invasion either into the lung tissue or into the general tissues of the body of the micro-organism or micro-organisms associated with the condition."

In a kindly annotation in your columns[3] my views were described as unorthodox, but so far as the belief that invasion of tissue plays no integral part in the attack, it would appear that this view is also held by Prof. McIntosh; but there we part company, for he explained the illness as due to a toxæmia. My clinical observations forbade the acceptance of a similar view for, being interested in the interpretation of symptoms, at the close of the epidemic I considered all the recognised symptoms recorded during the epidemic in relation to the history of each case, and stated:

> "If the pains in the limbs and region of the back are caused through a toxæmia, either by producing symptoms of exhaustion or by the toxins producing irritation of the muscle sheaths, then I cannot understand why those pains should disappear with the onset of the 'secondary' stage. . . . Because those pains cannot at present be explained from a physiological standpoint, that should give no justification for more or less dismissing them as a proof of toxæmia." (This was written long before the publication of Prof. McIntosh's report, and is not a criticism of his view.)

In searching for an explanation of those symptoms I was impressed with the similarity of those aches and pains to those which occur in extreme physical labour, and I wondered if they could not be explained on the basis of some metabolic disturbance which was essentially protective in type, a disturbance most probably of the nature of a retention of a normal product of katabolism. The interest I felt in Dr. Spaeth's original communication will be appreciated. How far this new communication of Dr. Spaeth bears on those opinions I do not ask for space to discuss here, for at the present time the essential points are that fatigue under certain conditions appears to raise the bodily resistance to infection, and that in an attack of influenza there are symptoms simulating fatigue which appear to be of good prognostic significance.

---

[2] Glasgow Medical Journal, October, 1922.
[3] THE LANCET, 1922, ii., 1083.

This work may also throw new light on the infantile convulsion and the rigor of adult life. For many reasons it is to be hoped that the untimely end of Dr. Spaeth may not lead to an abandonment of investigations into the relationship of fatigue to infection. His work deserves all the prominence which has been given to it through your leading article. I am, Sir, yours faithfully,

Halifax, Dec. 23rd, 1925. A. GARVIE.

## PROFESSIONAL CRITICISM OF THE GENERAL MEDICAL COUNCIL.

*To the Editor of* THE LANCET.

SIR,—In your issue of Dec. 26th Dr. Gordon Ward writes apparently with approval of an action on the part of medical men which would seem to me most reprehensible. I refer to his statement in regard to the signing of a "certificate which requires the doctor to certify that he has seen all the children of so-and-so alive on this date." I have long taught senior students and junior practitioners working under me that members of our profession are far too careless of the way in which they fill in certificates of all sorts, and warn them against signing their names in blank to any document or putting their signatures to any statement without first reading it carefully. The right to sign certain documents—such as applications for passports or for payment of pensions—is one which we share with justices of the peace and with members of a limited number of other professions. It is a right of which we should be proud, and carelessness in using our right should be avoided. This is, however, the first time that I have ever heard of a medical man openly stating that he is in the habit of signing such certificates knowing that he is making a false statement. Certainly I should call such behaviour both "fraudulent" and "unethical" (these are his actual words).

I am writing this because the layman who reads your paper should not be allowed to think that such a standpoint will go unchallenged. At any committee with disciplinary powers I, for one, should view with disfavour anyone who had made such a false statement by carelessness, and be prepared to recommend a severe penalty on anyone who was proved knowingly and intentionally to have done the same. I am, Sir, yours faithfully,

Welbeck-street, W., Dec. 26th, 1925. T. B. LAYTON.

---

*To the Editor of* THE LANCET.

SIR,—Will you allow me a word of friendly criticism of the leading article in your issue of Dec. 19th? In the course of that article you state that it is a British tradition that every trade and every profession is to manage its own affairs. Supposing I were a member of the black squad and, being democratic, I insisted on working for the wage offered by the employers, and that the other members of the trade-union did not agree to my doing so and forthwith proceeded to maul me. Am I not to be allowed to apply to the ordinary judicature of the country for reparation; is my case only to be considered by the trade-union? I do not agree to any such attitude whatsoever.

Now the General Medical Council as presently stablished is a law unto itself; in fact, if I read matters aright, it is superior even to the law of the land. It has a power which has not been held by any tribunal so far as I know since the Court of High Commission in the reign of James II. of England, that Court which directed the Bloody Assize in the West country. In some cases it appears to be very slack in its proceedings, in others unnecessarily severe. Many years ago a contribution which I made on the subject of seamen's eyesight, and which, with my consent, was published in the *Liverpool Journal of Commerce*, might even now get me into trouble. The General Medical Council may take it into its head even yet that such a contribution should not have been made to a lay journal. It was, however, an important contribution and stopped the adoption of certain regulations which would have put a very large number of competent men out of employment. Even at this moment I am anxious to make a communication on miners' nystagmus to an audience which would be composed chiefly of coal-pit managers and of the officials of the various unions. If the General Medical Council took it into its head it might say that that is an infamous thing to do. Naturally I believe that my communication will be of some value in helping to solve an extremely intricate economic problem. The General Medical Council is absolutely unconditioned; it may do what it likes, and nobody has any right to interfere with it. If THE LANCET thinks that that is a healthy state of matters I do not. I cannot go on with the publication meantime because one never knows what the General Medical Council will do.

It is all very well to say that a name can be reponed. So it can be, but meantime it has been struck off and the person involved has no doubt lost any appointments he may have held under the Crown, such as an appointment of certifying surgeon. He will likely also have lost any hospital appointment he may hold. As a rule, hospital appointments can only be held by persons who are on the Medical Register. When his name is reponed by the General Medical Council, will he also get back any medical appointments which he may have lost? Will they not meantime have been filled up so that it is impossible for him to regain his appointments? Unquestionably there should be an appeal to a competent legal tribunal before anyone is involved in perhaps financial ruin by amateur lawyers.

I have no wish whatever to disparage the General Medical Council. I think to some extent its constitution should be changed. But, given a right proportion of men who are of eminence in modern surgery and modern medicine, it is the proper body to determine the medical curriculum. To my mind it has recently made a mess of the curriculum. That, however, is a matter on which opinions may legitimately differ. But, given a sound working Council, whose members are for the most part in the prime of life and actively engaged in the higher parts of medical work, then it would be an admirable body for arranging the curriculum. The refusal to have an investigation rather conveys to my mind the idea that the cause of the General Medical Council is not a particularly strong one. Were it otherwise the Council would welcome a proper investigation.

My fear is that the discontent with the present organisation and powers of that body will cause its whole functions to be taken over by the Ministry of Health, and that is an event which I do not wish to occur. I think it can only be prevented by the General Medical Council insisting on an investigation and thereafter setting its house in order.

I am, Sir, yours faithfully,

Glasgow, Dec. 24th, 1925. FREELAND FERGUS.

*** The passage in our leading article, on which Dr. Fergus bases his argument, is not quoted quite correctly. The sentence ran: "Nor let it be forgotten that it is the British tradition to rely upon each trade or calling or service to maintain its own standards."—ED. L.

## PROFESSIONAL SECRECY.

*To the Editor of* THE LANCET.

SIR,—Recently I was asked to see a man-servant by his employer for some trifling ailment, and in due course the man was placed on my insurance list and the medical record card sent to me. From this I learnt that, a couple of years ago, the man was certified as insane and removed to an asylum. On the principle of "doing unto others as ye would that they should do unto you," I thought that the employer should be made aware of this fact, but before telling him I took the advice of an eminent medico-legal expert, whose opinion was quite definite that it would be highly improper of me to divulge these facts to the employer.

The position of a general practitioner in such a case seems to me to be very doubtful; for, apart from professional rules, it seems clear that the head of a household is entitled to be informed of any facts relating to the inmates' health which may lead to undesirable consequences as, for example, in the case of infectious diseases or lunacy. I should be glad to learn whether the profession generally adopts the view of my medico-legal expert. I may add that this confidential medical record card passed through two health insurance offices without a cover.

I am, Sir, yours faithfully,
X. Y. Z.

Dec. 27th, 1925

# Obituary.

## JAMES RITCHIE, M.D., F.R.C.P. & S. EDIN.

BY the death of Dr James Ritchie on Dec. 10th, in his eighty-fifth year, Edinburgh has lost one of the oldest and most respected members of the medical profession. Born in 1841, son of Andrew Ritchie, of Edinburgh, he was educated at the Royal High School and went on to study medicine at the Extra Mural School. He graduated M.B., C.M. Edin. with honours in 1872 and in the same year took the M.R.C.S. Eng. Two years later he became a Fellow of the Royal College of Surgeons of Edinburgh, and in due course a Member and Fellow of the Royal College of Physicians. Finally in 1891 he took the M.D. Edin. with a gold medal. This brilliant academic career was the forerunner of a very extensive practice in the town carried on up to recent years, when his retirement was deeply felt by many as the loss of a trusted friend and adviser. He held many appointments, chief among them the principal medical officership to the Scottish Metropolitan Assurance Company. At different times he was president of the Medico-Chirurgical and of the Obstetrical Societies of Edinburgh, and he was for many years examiner in midwifery to the R.C.S. Edin. His writings, which are to be found in the transactions of those societies, cover a large field of clinical observation. Dr. Ritchie was keenly interested in the affairs of the United Free Church of Scotland and held office for 62 years in posts filled by his father and grandfather before him. All his life he was a student of Nature and the leisure moments of a busy professional life were spent in gardening and sketching.

Dr. Ritchie married Jessie, daughter of Sir Thomas Clark, and is survived by two sons, both in the medical profession, and by four daughters.

## HENRY DUNN WAUGH, M.D., B.Sc. LOND.

Dr. H. D. Waugh, who died in London on Christmas Day after a short illness, was born at Bathgate in Scotland, and entered the Normal School, Wigtown, in 1861. After spending six years there he came to London and received further education at King's College School and University College, at which he graduated both in Arts and Science. In 1882 he qualified from University College Hospital as M.R.C.S. Eng. and held an appointment at the Victoria Hospital for Children. Later in the same year he went to Brompton Hospital for Consumption, where he was successively house physician and resident medical officer. This latter post he held more than five years, in the course of which time the junior residents in the hospital who had been under his authority passed to positions on the staff, remaining his friends in the latter capacity, as they had been in the former. Many patients also in the recurring conditions which marked a good many of the cases returned to the hospital more than once, to find Waugh still in authority and making an ever kindly link between the past and present. There is no doubt that his long tenure of this important post enabled him to form and cement many abiding friendships. It was not until 1889 that he left the hospital, after taking his M.D. degree at London University, and entered general practice in the West End of London. Amongst his recreations was climbing, and he was a member of the Alpine Club.

## JOHN GOUGH NOLAN, M.B., CH.B. MANCH.

Dr. Nolan, deputy police surgeon for Wigan, died suddenly at his residence in Wigan from a heart affection on Dec. 15th. A native of Southport, he received his early education at St. Edward's College, Liverpool. He studied at the University of Manchester and Dublin, qualifying M.R.C.S., L.R.C.P. Lond. in 1919, and in the same year graduated M.B., Ch.B. (with distinction in surgery) at the University of Manchester. He obtained the Dunville Surgical Scholarship, and before going to Wigan he was senior house physician and surgeon in the Royal Infirmary, Manchester, resident medical officer at the Northern Hospital for Women and Children, Manchester, and assistant medical officer at Barnes Convalescent Hospital, Cheadle, Cheshire. He was assistant honorary surgeon to the Wigan Rugby F.C. Dr. Nolan was in his thirty-second year and unmarried. At the inquest the coroner paid a high tribute to the work—public and private—which he had accomplished in Wigan before his life was prematurely cut short.

## JOHN JAGGER PICKLES, M.R.C.S. ENG.

Dr. J. J. Pickles, sen., who died at his son's house at Leyburn on Dec. 21st, was born at Shelf, near Halifax, in 1851. He was educated at Hipperholme Grammar School and at Leeds Medical School, where he was gold medallist for his year. Qualifying as M.R.C.S. Eng. in 1873 and L.R.C.P. Edin. in 1874, he held resident appointments at the Leeds General Infirmary and at Bradford Infirmary. He became a general practitioner in the Camp Road district of Leeds, and remained at work there for 50 years. As a medical man he was a general favourite, and his relations with his professional brethren were unusually cordial. He was honorary surgeon to the Leeds Tradesmen Benevolent Society, and as an enthusiastic steward of the Medical Charitable Society for the West Riding of Yorkshire was always ready where to urge its claims on those who were eligible for election. His loyalty to the Leeds School of Medicine was shown by the fact that the five of his six sons who became doctors obtained their qualifications there. All his sons served in the war, and four survived. His wife died eight years ago. Dr. Pickles will be long remembered in medical circles in Leeds as a genial and straightforward colleague.

## JOHN FRANCIS McCLEAN, M.R.C.S. ENG.

Dr. J. F. McClean, senior resident medical off of the London Fever Hospital, died at St. Thom Hospital from septicaemia following an injury to hand. He was educated at St. Thomas's Hosp and held the appointments of house surg [illegible] obstetric house physician there after [illegible] M.R.C.S. Eng., L.R.C.P. Lond. in 1897 [illegible] [illegible] of the British [illegible] [illegible] and for many years [illegible] in the British Hospital in Constan [illegible] [illegible] by the Turk

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *The Christmas Recess.*

PARLIAMENT was prorogued by Royal Commission in the House of Lords on Tuesday, Dec. 22nd, 1925. It will reassemble for the new session on Feb. 2nd next.

## HOUSE OF COMMONS.

### MONDAY, DEC. 21ST.

### *Illicit Cocaine Traffic in Bombay.*

Colonel DAY asked the Under-Secretary of State for India whether there had been any prosecutions in Bombay for the three months ending Nov. 30th for the illicit sale of cocaine; and, if so, would he state the names of the defendants and the punishment inflicted on them if they were convicted.—Earl WINTERTON replied: Current reports of such cases are not officially received except of those arising from Customs seizures at the ports which are required for communication to the Secretariat of the League of Nations. Four cases under this head have occurred since August 31st, 1925, and led to convictions. I have seen reports in the press of the recent case in which three men appear to have been convicted and sentenced respectively to nine months' rigorous imprisonment and a fine of Rs.1000, to four months' rigorous imprisonment and a fine of Rs.500 or a further three months' imprisonment, and to three months' rigorous imprisonment and a fine of Rs.500 or three months' further imprisonment. The following is a statement regarding prosecutions arising from seizures of cocaine by the Customs authorities at Bombay, giving initials of accused, date of arrest, and sentence:—

T. O., August 31st, 1925, nine months' rigorous imprisonment.

R. M., Sept. 7th, 1925, fine of Rs.250, or three months' imprisonment (the fine was paid).

K. T., Sept. 16th, 1925, six months' rigorous imprisonment.

F. M., Sept. 28th, 1925, nine months' rigorous imprisonment, and fine of Rs.1000, or three months' rigorous imprisonment (the fine was paid).

### *Medical Services in East Africa.*

Sir SYDNEY HENN asked the Secretary of State for the Colonies what steps were being taken to strengthen the medical services throughout East Africa; and what was the attitude towards recruitment in this country for such services adopted by medical schools and societies.—Mr. AMERY replied: It is not possible to give definite figures pending consideration of the estimates of the various Dependencies for the coming financial year, but I anticipate a considerable further extension of medical work in Eastern Africa in the near future, especially in Kenya, Uganda, and the Tanganyika Territory. It is hoped to increase the personnel of the East African Medical Service by some 20 or 30 officers during the next year. The attitude towards recruitment adopted by the medical schools and societies has been very helpful in the past, and I hope to secure their coöperation in filling up the many new appointments which are about to be created.

### *Native Infant Mortality in Tanganyika.*

Sir SYDNEY HENN asked the Secretary of State for the Colonies whether his attention had been called to the rate of native infant mortality disclosed at the recent education conference at Dar-es-Salaam; and what steps were being taken, or would be taken, to deal with the matter.—Mr. AMERY replied: I am aware of the high rate of infant mortality in Tanganyika Territory. Active measures are being taken to improve medical and sanitary conditions. The number of medical officers has been increased by 12 this year and numerous native assistants, including sanitary inspectors and nurses, are being trained.

### *Poor-law Reform.*

Mr. BRIANT asked the Prime Minister if, in view of the divergence of opinion on the proposals for Poor-law reform outlined by the Minister of Health and the opposition which had been evoked, notwithstanding the general desire for an alteration in the methods of relief of distress, he would consider the desirability of appointing a committee of Members of the House, representing all parties, in order to ascertain if it was possible to arrive at an agreed measure on the subject.—Mr. BALDWIN replied: My right hon. friend has adopted the plan of publishing his provisional proposals with the express object of obtaining suggestions from those experienced in local government and Poor-law administration, which will lead to a scheme commanding as large a measure of agreement as is possible in a matter of this kind. I do not think that such a committee as th hon. Member proposes is desirable at the present time.

### *Lunacy and Mental Disorder.*

Mr. AMMON asked the Prime Minister what action h proposed to take with regard to the memorial sent to hi in May last, signed by 90 Members of Parliament, wit reference to the Royal Commission on Lunacy and Menta Disorder now sitting.—Mr. BALDWIN replied: On May 30th I wrote to my hon. friend the Member for Exeter (Sir R Newman), who had forwarded this memorial to me, an informed him that the Royal Commission have a complete discretion regarding the procedure they adopt in the con duct of their inquiry, and that I am not, therefore, in a position to give any directions in the matter. At the same time, I informed my hon. friend of some of the considerations which had weighed with the Royal Commission in determining their procedure, and which appeared to me fully to justify the course which they have adopted in their inquiry.

### *Epileptic Patients at Maghull.*

Mr. HAYES asked the Minister of Pensions whether any curative treatment other than four and a half hours' work daily was provided for the epileptic patients at the Ministry of Pensions Hospital, Maghull; whether he was aware that the patients were allowed group leave from 12.45 until 3.15 P.M.; that the midday meal was given before leave was taken; and that men taking leave in groups of three or more, in the event of one of the patients having a fit, the others must leave him or run the risk of being punished for being out over the leave hours; and whether, in the cases where men were fined 3*s.* to 6*s.* for being out after leave had expired, the deductions were stopped from the allowance paid to the wives.—Major TRYON replied: The treatment for epilepsy at this institution includes all the known curative and ameliorative methods. The four hours' leave granted is the maximum under the regulations which apply to all Ministry hospitals. It rests with the medical superintendent to determine at what time leave shall be taken in suitable cases. Where leave was overstayed in the circumstances referred to the medical superintendent would not regard the matter as one of misconduct. With regard to the last part of the question, any fine imposed for misconduct is, under the rules of the Ministry, payable from the personal allowance due to the man only, and not from any allowances payable to his wife and family.

### *Dental Benefit for Insured Persons.*

Mr. WARNE asked the Minister of Health whether the Ministry recognised the specifications issued to approved societies by the Public Dental Service Association as suitable to enable a standard denture to be supplied to insured persons; in view of the varying kinds, qualities, and prices of materials to be used in the making of dentures, had the Ministry of Health introduced any scheme for ensuring dental treatment and dentures of a standard price and quality as in the case of medical benefit—e.g., chemicals, materials, and appliances supplied by the doctors, chemists, and druggists; and had the Ministry defined by statute, under Section 75 (5) of the National Health Insurance Act, 1924, dental treatment as being in the nature of medical benefit.—Mr. N. CHAMBERLAIN replied: The specifications in question which represent the results and negotiations between representatives of the dental profession and of certain approved societies do not require, and have not received, any recognition from my Department. As regards the second part of the question, I have no power under the existing Acts to make regulations on the lines suggested by the hon. Member. As regards the last part, I am advised that having regard to the terms in which this benefit is defined in the Acts, it is not a benefit in the nature of medical benefit for the purposes of Section 75 (5).

### *Medical Branches of the Services.*

Major-General Sir FREDERICK SYKES asked the Prime Minister whether he would set up a committee to consider the present possibilities of reorganising the three medical services in the fighting forces into a unified service.—Mr. BALDWIN replied: The question of the amalgamation of the medical branches of the three fighting services was carefully considered by His Majesty's Government some two or three years ago, when it was decided that this step was undesirable. A Standing Joint Committee on which the Ministry of Pensions Medical Department is also represented has been set up to discuss matters affecting the medical services of the four departments. The question of the pay of officers of the medical branches of the three fighting services, and all matters ancillary thereto, is at present being considered by a committee set up for the purpose as indicated in the reply given on Nov. 10th.

### *Cost of Military Hospitals.*

Major-General Sir FREDERICK SYKES asked the Secretary of State for War if he would state in respect of hospitals under his administration in this country and elsewhere, respectively, the estimated capital value of lands and of buildings occupied; the annual building maintenance cost, the annual cost of medical stores, the annual cost of provisioning; the annual cost of, and the numbers of staff employed on, medical services; the annual cost of, and the numbers of staff employed on, services other than medical and building maintenance; the annual cost of any additional staff or services; the maximum patient accommodation; and the maximum and average number of patients in residence in any one day in the last 12 months.—Sir L. Worthington-Evans replied: So far as they are available the figures are as follows:—

| | Home. | Abroad. |
|---|---|---|
| Estimated— | | |
| Capital value of lands and buildings | £1,000,000* | £500,000* |
| Annual building maintenance cost | £25,000 | £17,500 |
| Annual cost of medical stores | £21,000 | £11,000 |
| Annual cost of provisioning patients | £63,000 | £38,000 |
| Annual cost of staff | £375,000 † | £198,000 † |
| Numbers, ditto | 1,800 | 950 |
| Average daily number of equipped beds during year ended Nov. 30th, 1925 | 4,340 | 2,118 |
| Maximum number of beds occupied during same period on any one day | 3,717 | 1,877 |
| Average, ditto | 2,304 | 1,130 |

* These are very rough estimates and are given with reserve.

† The numbers and cost of those engaged on (*a*) medical and (*b*) other services, cannot be given separately. Personnel engaged on building maintenance are not included.

The hon. and gallant Member may like to refer to the very full information on pages 60 and 61 of the Army Accounts for 1923–1924.

### *Cost of Air Force Hospitals.*

Major-General Sir Frederick Sykes asked a similar question with regard to Air Force hospitals.—Sir S. Hoare replied: The following statement gives the information requested by my hon. and gallant friend:—

| | Home. | Abroad. |
|---|---|---|
| 1. Capital cost of lands and buildings | £102,455 | £700,000 |
| 2. Annual building maintenance cost | £2,000 | £10,000 |
| 3. Annual cost of medical stores | £7,000 | £9,000 |
| 4. Annual cost of provisions | £7,770 | £21,000 |
| 5. Annual cost of staff employed on medical services | £19,000 | £98,000 |
| Numbers of such staff | 239 | 337 |
| 6. Annual cost of staff employed on other than medical and building maintenance | £3,000 | £14,000 |
| 7. Numbers of such staff | 17 | 309 |
| 8. Annual cost of any additional staff or services | £6,000 | £25,000 |
| 9. Maximum patient accommodation | 447 | 900 |
| 10. Maximum number of patients in residence on any one day in last 12 months | 437 | 544 |
| 11. Average number of patients in residence during last 12 months | 109 | 329 |

As regards (1) above, £650,000 of the figure in the second column represents the capital cost of hospitals in Iraq, which were largely built under Army administration before the reduction of the garrison to its present size. A reassessment of the present value has not been undertaken. As regards (8) above, the figures of £6,000 and £25,000 represent cost of water, heating, lighting, and conservancy services. As regards (9), the 900 beds abroad do not include a possible expansion of 239 beds at Basrah Hospitals (British and Indian). The hospitals at Hinaidi are also capable of a very large expansion within the existing buildings. As regards (9), (10) and (11), the hospitals in Iraq cater for the whole of the garrisons—i.e., British and Indian Army troops—in addition to R.A.F. personnel; the same is the case in Palestine, where the hospitals also provide for the British Gendarmerie. Further, it should be borne in mind that the garrisons in Iraq and Palestine have been largely reduced in the past few years and are still in process of reduction.

### *Sealing of Milk Churns.*

Mr. Herbert Williams asked the Minister of Health whether he had received application from any local authority for power to order the sealing of milk churns containing milk in transit from producer to retailer; and, if so, what action was being taken by the department.—Sir Kingsley Wood replied: My right hon. friend has received a number of communications suggesting that a Milk and Dairies Order should be made requiring the sealing of milk churns, and he is in consultation with the Minister of Agriculture and Fisheries in the matter.

### *Naval Medical Boards.*

Mr. Thomas Williams asked the First Lord of the Admiralty if he was aware that recently there were ten or more ex-naval officers and men inmates of the Meathop Sanatorium, some of them with 20 years' service; that a medical board took place which consisted of an examination by one doctor, and that the findings in each case were that the disability was constitutionally not caused by nor aggravated by service; and, in view of the loose term and the dissatisfaction among these ex-officers and men, would he cause inquiries to be made into some of these cases and remove any doubts that might exist.—Mr. Davidson (Parliamentary Secretary to the Admiralty) replied: Naval cases of tuberculosis are invalided by Board of Survey at naval hospitals. In a very few instances, however, where the patient has already entered a sanatorium prior to coming under naval observation, it may be necessary to hold a survey with a view to invaliding without causing the patient to be moved. This survey may be carried out by the Admiralty surgeon and agent of the district in conjunction with the sanatorium authorities. The report of such survey would be examined by the Naval Medical Department at the Admiralty before action is taken, in a similar manner to that adopted for other naval medical surveys. I have no information as to the cases of tuberculosis in Meathop Sanatorium to which the hon. Member refers, but if the names of any special cases he may have in mind are furnished to me I will cause inquiry to be made.

## TUESDAY, DEC. 22ND.

### *Notification of Diphtheria and Scarlet Fever.*

Mr. Bromfield asked the Minister of Health whether he was aware that 31·5 per cent. of the cases notified as diphtheria, and 13·0 per cent of the cases notified as scarlet fever, and sent to the infectious diseases hospitals of the Metropolitan Asylums Board in the year 1924, were found after admission to be suffering from something else or from no disease at all; whether there was any reason to believe that these percentages were as great or greater throughout the country; whether any steps were taken to correct the statistics of notification for these errors; whether the parents of the children were informed as to the mistaken diagnoses; whether there was any information available as to how many, if any, of these cases contracted diphtheria or scarlet fever after admission to hospital; whether the practitioners who made these errors were called upon to refund the notification fees received by them; and, if not, would he consider the desirability of arranging for that course to be adopted.—Mr. N. Chamberlain replied: The answer to the first part of the question is in the affirmative, but I may say that I am informed that the increase in the number of cases of diphtheria admitted during 1924 to the infectious diseases hospitals of the Metropolitan Asylums Board in which the diagnosis had to be revised may be accounted for by the increasing recognition on the part of medical practitioners of the necessity, in the interests of the patient, of immediate removal to hospital for the purpose of receiving treatment as early as possible without waiting for the receipt of a laboratory report. As regards the second part of the question, no figures are available for the country as a whole which would enable any definite conclusion to be arrived at. As regards the third part, I am informed that in cases in which the diagnosis made at the Metropolitan Asylums Board's hospitals is not in agreement with that of the notifying practitioner, the information is communicated to the medical officer of health of the sanitary district from which the patient was removed in order to ensure the accuracy of his statistics. As regards the fourth part, I understand that information as to the diagnosis made at the hospital is given to the parents on request. As regards the fifth part, I am informed that there is no information available as to the number, if any, of these cases which contract scarlet fever or diphtheria after admission to hospital. As regards the last part of the question, I am advised that there is no statutory provision under which a medical practitioner could be called upon to refund the fee for a notification certificate in a case in which his diagnosis is not in agreement with that subsequently made at the hospital, and in view of what I have said in replying to the first part of the question, it would, in my opinion, be undesirable in the public interest that such a course should be adopted.

### *Deaths from Encephalitis Lethargica.*

Captain Fairfax asked the Minister of Health, in view of the figures given by his department, which show 330 deaths from encephalitis lethargica in 1922, 531 in 1923, and 1107 in 1924, what the figures were for 1925 up to date; and whether any measures had been taken, or were in contemplation, to prevent the increase of this fatal complaint.—Sir K. Wood (Parliamentary Secretary to the Ministry of Health) replied: 1157 deaths have been provisionally attributed to this disease in England and Wales during 1925, up to the end of October. As regards the second part of the question, my right hon. friend's department has issued several reports and memoranda in recent years in which the principal facts ascertained regarding the occurrence of this disease and the manner of its spread have been set out. Efforts are being made in conjunction with the Medical Research Council to add to our knowledge of the causes of this disease and the possibilities of avoiding it.

# Medical News.

University of Oxford.—The Board of Faculty of Medicine has coöpted E. Farquhar Buzzard, D.M., Magdalen College, and Malcolm H. MacKeith, D.M., Fellow of Magdalen College, as members of the Board for two years. The Francis Gotch Memorial Prize in Physiology for 1925 has been awarded to Joyce Wright, B.A., Somerville College. Proxime accessit: Jack Wynne Pugh, B.A., University College.

University of Cambridge.—At recent examinations the following candidates were successful:—

Third Examination for Medical and Surgical Degrees.

*Part I., Surgery, Midwifery, and Gynæcology.*—A. R. Adderley, D. Aserman, G. W. Bamber, J. O. W. Bland, G. C. W. Brown, J. A. S. Brown, P. R. Buckton, G. P. Chandler, P. F. Chandler, H. A. Clegg, L. C. Cook, W. F. Cooper, R. Cunningham, T. S. Dewey, H. V. Dicks, J. Dockray, C. E. Donaldson, A. B. Eddowes, J. B. Ellison, A. W. Ewing, T. D. W. Fryer, S. J. P. Gray, J. C. P. Grey, W. S. Grove, H. J. Heathcote, J. D. Hindley-Smith, G. G. Holmes, J. H. Humphris, I. A. Jackson, D. McI. Johnson, S. Levy Simpson, A. V. Mackenzie, Hon. W. S. Maclay, R. D. Milford, H. L. Milles, W. J. Moody, R. T. Mummery, H. P. Nelson, H. E. Nourse, F. B. Parsons, W. R. H. Pooler, J. D. Procter, L. A. Richardson, R. Riley, J. B. W. Roberton, M. E. D. Roberts, F. C. Roles, G. L. F. Rowell, H. Scudamore, C. J. L. Sharp, G. Simon, R. E. Smith, A. W. Spence, G. M. Tanner, B. C. Tate, G. K. Taylor, H. B. Trumper, J. G. Wigley, H. L. Wilson, R. M. Windeyer, F. G. Winterton, A. T. Worthington, and H. R. Youngman.

*Part II., Physic, Pathology, and Pharmacology.*—D. Aserman, G. W. Bamber, W. A. Barnes, I. C. P. Beauchamp, J. A. S. Brown, Hon. C. B. Buckley, N. F. C. Burgess, R. T. Chadwick, H. A. Clegg, A. C. Copley, R. W. Cuningham, G. H. Day, G. W. S. de Jersey, J. H. Gibbens, N. T. Glynn, R. F. Guymer, C. C. Halliwell, J. C. Hogg, A. T. Howell, W. S. Hunt, J. W. W. Jepps, D. F. Lawson, G. A. Q. Lennane, L. J. Panting, W. R. H. Pooler, R. L. Rhodes, F. R. Sandford, E. M. Shackel, A. Simpson-Smith, H. B. Stallard, E. J. E. Topham, E. A. Trim, J. L. Warner, and H. M. Woodman.

University of London.—At the recent examination for the degree of Master of Surgery John Basil Hume, of St. Bartholomew's Hospital, was approved by the examiners.

University of Durham.—At the Convocation held on Dec. 19th the following degrees and diplomas were conferred:—

Master of Surgery.

James Whillis and Angus H. Whyte.

Bachelor of Medicine and Bachelor of Surgery.

Norman Davison, James W. Dickinson, Basil A. Dormer, Alan Gray, Louis Lavine, Richard A. Pallister, Ernest P. Pratt, Winifred M. Proctor, William S. Walton, and James Y. Woodhouse.

Bachelor of Hygiene.

Ian M. McLachlan.

Diploma in Public Health.

Ian M. McLachlan.

University of Liverpool.—At examinations held recently the following candidates were successful:—

Degree of M.D.

F. S. Fowweather, W. D. Jeans, R. J. Minnitt, M. Newman, and C. Voigt.

Degrees of M.B. and Ch.B. (Honours).

*Class I.*—C. A. Birch (distinction in Medicine and Obstetrics).

Final Examination for Degrees of M.B., Ch.B.

*Part III.*—A. Ashworth, Ethel Barrow, C. Baxter, E. I. Bieber, P. V. Dillon, F. R. Faux, J. H. Gilchrist, R. I. Greenshields, J. Hatton, Enid M. Hughes, T. S. L. Jones, Rebecca Katz, B. Kay (distinction in Obstetrics), Alice M. Luck, D. D. O. McLoughlin, Lilian W. Massey, J. Morrissey, E. R. S. Owen, W. J. Pierce, Thirza Rodman, D. Roberts, F. B. Shevlin, P. Strelitz, J. Tarshish, J. E. C. Walker, and W. L. Webb.

*Part I.*—A. B. Anderson, J. H. Boultbee, W. S. Brindle (with distinction), A. N. Cameron, J. K. Cameron, E. Cohen, W. S. Creer, A. Dodd, W. J. Eastwood, K. Edmundson, Elsie A. Griffiths, I. Gurland, E. D. Irvine, R. N. Johnson, O. V. Jones, Theresa J. Lee, J. L. Lewis, F. E. Lomas, J. McHugh, S. G. Massey-Lynch, J. W. Pickup, A. D. Polonsky, C. Rigby, N. W. Riley, G. L. Roberts, Alfreda H. Slater, V. J. M. Taylor, J. P. Thomas, S. L. Tunnicliffe, D. P. de Villiers, E. N. Wardle (with distinction), P. H. Whitaker, and R. L. Wynne.

*Part II.*—Grace A. Austin, W. A. Davies, J. Halton, W. E. Hargreaves, S. P. Meadows (distinction in Forensic Medicine), J. Morgan, J. N. Parrington, E. S. Smith, and Joan Watkins.

Second Examination for Degrees of M.B., Ch.B.

*Part A.*—S. Alstead, E. T. Bates, *R. K. Bowes, S. Canter, J. H. St. B. Crosby, *T. B. Davie, Ariel R. S. Deacon, †T. L. Dowell, R. Doyle, H. R. Dugdale, J. H. Follows, R. A. Furniss, Agnes G. Gillespie, R. G. Gornall, J. J. Graham, G. T. Harris, E. W. Jones, Mary G. Jones, W. E. J. Jones, †T. Lasker, N. R. Lawrie, J. M. Leggate, H. Leiper, C. T. Mercer, Doris Morrison, H. Paterson, Elizabeth R. Robson, E. L. Rubin, †M. Silverstone, H. W. Smith, G. A. Talwrn-Jones, G. G. Warburton, and F. J. Welton.

* Distinction in Anatomy and Physiology. † Distinction in Physiology.

*Part B.*—S. W. Adler, Gladys A. Coventry, A. Dala, R. E. Jackson, K. Jilani, I. Kossow, T. C. Newman, G. W. Phillips, E. E. Prebble, and A. L. Williams.

Diploma in Tropical Medicine.

A. R. D. Adams, F. R. Ashton, Esther Ashworth, C. W. Bamford, J. Belnashowitz, G. Clark, B. A. Coghlan, Ivy Collier, P. G. Cumming, M. Fisher, M. S. Grutu, A. J. Hawe, Z. H. Jafri, Elvy I. Johnstone, J. R. Kerr, D. M. Mackay, M. M. el Makkawi, L. G. Maldonado, S. F. Mar, B. P. Mozoomdar, D. A. Skan, E. R. Stone, C. G. Terrell, and F. Tooth.

Recommended for Milne medals: Dr. Adams and Dr. Hawe.

University of Birmingham.—At a Congregation held recently the following degrees were conferred:—

*Doctor of Medicine.*—Mabel Thorburn Johnstone, Horace Simkin Savage.

*Bachelor of Medicine and Bachelor of Surgery.*—Dennis Murray Bladon, Zaki Ahmed Goma, Constance Rougier La Trobe, Margaret Elizabeth Lovett, Dorothy May Payton.

University of Dublin, Trinity College.—It is proposed to celebrate the centenary of the new medical school early in January. The building of the new school was begun in 1823 and it was formally opened on Nov. 1st, 1825, by Prof. James Macartney, university professor of anatomy and chirurgery. On Wednesday, Jan. 13th, Dr. T. P. C. Kirkpatrick will deliver an address on the Early History of the School of Physic at a meeting to be held in the school, at which the Provost will preside. All medical graduates of the University are invited to be present. On the same evening a dinner will be held in the dining hall of the College at 7.15 P.M., for which medical graduates may obtain tickets at £1 1s. each. Academic dress will be worn. Accommodation is limited and applications for dinner tickets should be made as early as possible to the Dean of the Faculty of Physic, Trinity College, Dublin.

Territorial Army Medical Officers Association.—A dinner for Territorial medical officers, active and retired, will take place at the Café Royal, 68, Regent-street, London, W., on Friday, Feb. 12th, at 8 P.M. Officers proposing to attend are requested to communicate without delay with Colonel M. B. Ray, D.S.O., M.D., at 37, Russell-square, London, W.C.1. Lieut.-General Sir Hugh Jeudwine and Lieut.-General Sir William Leishman have intimated their intention to be present.

Lecturers to Midwives.—Post-certificate lectures arranged by the London County Council for 1926 are to be given in Northern London by Mr. T. W. Letchworth, Dr. Eric Pritchard, Dr. Janet Lane-Claypon, Mr. Alfred Richardson, Dr. T. Anwyl-Davies, Mr. J. M. Wyatt, and Dr. G. F. Stebbing, and in Southern London by Dr. W. Brander, Mr. Trevor Davies, Mr. Leonard Phillips, Mr. Leslie Williams, Mr. M. S. Mayou, Dr. Remington Hobbs, and Dr. Archibald Gray.

Royal Institute of Public Health.—The Council have awarded the Harben Gold Medal for 1925 (triennial), of the value of 50 guineas, to Prof. Baron Shibasaburo Kitasato, M.D., Director of the Royal Japanese Institute for Infectious Diseases, for his "eminent services to the public health." The Council have also made the Smith Award to Prof. Matthew Hay, M.D., LL.D., F.R.C.P. Irel., for his "outstanding merit as a medical officer of health." The Smith Award takes the form of a bronze statuette of Hygeia by Charles L. Hartwell, R.A., which was exhibited at the Royal Academy in 1910.

British Institute of Philosophical Studies.—A course of nine lectures on Life and Mind will be given by Prof. James Johnstone on Mondays at 5.30 P.M. at the Bedford College for Women, Regent's Park, N.W. The course will begin on Jan. 11th, and the fee will be £1 5s. Twenty lectures on Science and Philosophy—the Conception of Matter—will be given by Prof. Leonard J. Russell on Tuesdays at 5.30 P.M. from Jan. 12th onwards at the same place. The fee for this course will be £2 2s., and in both cases members of the Institute will be charged half fees only. A full syllabus can be obtained from the Director, 88, Kingsway, London, W.C. 2.

BRITISH INDUSTRIES FAIR.—This fair will open concurrently in London and Birmingham in February next, and will include exhibits of chemicals and a variety of machinery and manufactures.

PHARMACEUTICAL SOCIETY.—The third evening meeting of the session will be held in the lecture theatre of the Society's House on Tuesday, Jan. 12th, at 8 o'clock, when Frank Browne, F.I C., and Dorothy G. Randle will read a paper on Some New, Modified, and Tested Formulæ of the British Pharmaceutical Codex.

WELSH HOSPITALS DINNER.—A reunion dinner for all ranks will be held at the Royal Hotel, Cardiff, on the evening of Jan. 16th. Colonel A W. Sheen will preside, and owing to the international match at Cardiff on that date a large attendance is expected. Tickets and further particulars can be obtained from Staff-Sergeant R. W. Hedley, Waterworks Department, City Hall, Cardiff.

FROM next Monday, Jan. 4th, all persons who are required to be insured under the National Health Insurance Act must also be insured under the Widows', Orphans' and Old Age Contributory Pensions Act. Health and pensions contributions will be paid on one card by means of combined health and pensions stamps which can be purchased from any post office.

RONTGEN SOCIETY.—A general meeting will be held on Jan. 5th, at 8 15 P.M., in the British Institute of Radiology, 32, Welbeck-street, London, W. Dr. G. W. C. Kaye will read a paper on a Combined X Ray Tube and Vacuum Pump Unit, and one on the Industrial Uses of X Rays. Mr. A. F. Dufton will speak on the Measurement of Radium during Radioactive Growth.

WIRELESS AT ST BARTHOLOMEW'S HOSPITAL.—A wireless installation, presented by the Radio Communication Co. through the *Daily News* fund, was inaugurated at St. Bartholomew's Hospital last week. The 612 head 'phones which, in addition to two loud speakers, comprise the reception equipment, were given by the British Thomson-Houston Co.

ROYAL SALOP INFIRMARY.—The Marchioness of Cambridge has laid the foundation-stone of a new children's wing of the Royal Salop Infirmary at Shrewsbury which will cost £20,000. The extension will provide 30 beds immediately and 40 others later on.

THE "DAILY MAIL" HOSPITAL BALLOT.—Lord Knutsford, presiding at the annual meeting of the British Charities Association, said that the surplus on the *Daily Mail* Hospital Ballot amounted to over £87,000, the highest result of any project conducted under the auspices of the Association. Last year the Association allocated £15,000 to the London Ho pital; this year the amount has been £20,000.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART Special intensive courses in cardiology, of a fortnight's duration, are held at this hospital in January, July, and October every year; the first of these courses for the year 1926 will begin on Monday, Jan. 18th. The fee for the course, which is strictly limited to 10 members, will be £7 7*s*. A copy of the syllabus and full particulars may be obtained from the Secretary at the hospital, Westmoreland-street, London, W. 1.

DENTAL BOARD OF THE UNITED KINGDOM.—The fourth and last of the series of post-graduate lectures, illustrated by lantern slides, on General Anæsthesia, arranged by this Board will be delivered by Prof. Noel Paton, F.R.S., on the Metabolic Changes in Chloroform Poisoning, at the following places: In London, at the house of the Royal Society of Medicine, 1, Wimpole-street, W., at 8.30 P.M., on Jan. 11th; in Manchester, at the Medical School, University Buildings, Oxford-road, at 5.30 P.M., on Jan. 13th; and in Edinburgh, in the Surgery Theatre of the University, at 6 P.M., on Jan. 15th. The course is intended primarily for dentists and medical practitioners. Dental students are invited to attend. Tickets of admission are not required. It is the intention of the Board to publish these lectures in volume form early this year.

Messrs. J. and A Churchill announce that they are publishing this week a new work entitled "The Nematode Parasites of Vertebrates," by Dr. Warrington Yorke, professor of parasitology, University of Liverpool, and the Liverpool School of Tropical Medicine, and Dr. P. A. Maplestone, lecturer in the same school. About 900 figures will illustrate the work, and the object of the authors has been to provide a reliable guide to the allocation of parasites to their genera. A fourth edition of Prof. E. H. Starling's "Principles of Human Physiology" is also to be issued. It has been thoroughly revised and now contains 570 illustrations, 10 of which are in colour. "Recent Advances in Obstetrics and Gynæcology," by Mr. Aleck W. Bourne, obstetric surgeon, St. Mary's Hospital, is now ready.

Mr. Lionel de Rothschild has become President of the Hospital for Diseases of the Throat, Golden-square.

COVENTRY HOSPITAL SATURDAY FUND.—The Hospital Saturday collection in Coventry this year produced £22,025, and a hospital carnival yielded £3100 in addition.

LONG WAITING LISTS.—At the annual meeting of the Edinburgh Royal Infirmary Samaritan Society it was stated that on Dec. 1st last there were 2220 persons on the waiting list of the infirmary, and that two deaths had occurred on account of the delay in admission. At the Leeds Infirmary there is a waiting list of 1700.

METROPOLITAN HOSPITAL SUNDAY FUND.—At a meeting of the Metropolitan Hospital Sunday Fund, held recently at the London Mansion House under the presidency of the Lord Mayor, Sir William Pryke, June 27th was fixed as the date on which the annual collection will take place this year. The sum collected on Hospital Sunday in 1925 was £91,811, the fourth highest on record. £81,620 were distributed among 227 institutions. Of the total collections 10 *per cent.* was appropriated to nursing homes and the purchase of surgical appliances.

INSTITUTE OF PSYCHO-ANALYSIS.—The following courses of lectures will be given to medical practitioners and medical students at the Examination Hall, Queen-square, W.C., on Friday evenings at 8.30 P.M., starting on Jan. 15th. The first three lectures on the Unconscious will be given by Mr. J. C. Flügel. Dr. Ernest Jones will then give six lectures on the Theory of Sexuality, to be followed by six lectures by Dr. James Glover on the Psycho-pathology of Anxiety States, Phobias, and Obsessions. Further particulars can be obtained from Dr. John Rickman, 20, Devonshire-place, W. 1.

CENTRAL ASSOCIATION FOR MENTAL WELFARE.—A course of eight medical lectures on Mental Disorders and their Early Treatment will be given in the Lecture Hall of the Six Point Group, 92, Victoria street, S.W., on Wednesdays, at 5.30 P.M., beginning on Jan. 6th. The lectures are intended especially for social workers interested in mental welfare. Dr. T. Beaton will deliver the first lecture, entitled the Nature of Mental Disorder and its Relation to Insanity, and the two following ones on Psychology. Dr. E. Mapother will give two lectures on Clinical Types of Mental Disorder and one on Methods of Treatment of Mental Disorders. The final lectures of the course, on Delinquency in Children and Methods of Investigation, will be given by Dr. E. A. Hamilton Pearson. Further particulars may be obtained from the Hon Secretary of the Association at 24, Buckingham Palace-road, London, S.W. 1.

DONATIONS AND BEQUESTS.—Mrs. Mary Anne Traill, formerly of Brighton, bequeathed £500 to the Royal Sailors' Rest, Portsmouth; £300 to John Groom's Crippleage and Flower Girls' Mission; £200 each to St. Dunstan's Hostel for the Blind, the Cripples' Home for Girls, Marylebone-road, the East London Hospital for Children, the Royal Surgical Aid Society, and the Boy Scouts' Fund; and £100 each to the Hospital for Women, Soho, the Royal Ophthalmic Society, City-road, and St. Mark's Hospital, City-road.—An appeal by the Mayor of Birkenhead on behalf of the local hospitals has reached £1500. In addition a collection made at Cammell Lairds yards on the occasion of the launch of H.M.S. *Rodney* amounted to £310.—The late Mr. T. R. Bolitho left by will, in addition to other bequests, £200 to the West Cornwall Infirmary; £100 each to the Liskeard Cottage Hospital; the Edward Main Hospital, St. Ives; the Miners' Hospital, Redruth; the Helston Dispensary; the Royal Cornwall Sailors' Home and Infirmary, Falmouth; the Royal Cornwall Infirmary, Truro; the Penzance branch of the Charity Organisation Society, and the Penzance Rescue and Preventive Society.—Mr. Hugh Shearwin Hemsley, of Hornsea, formerly of Headingley, Leeds, among other bequests, gave £3000 to the Wesleyan Methodist Foreign Missionary Society, as to £1250 thereof to be for medical missions connected therewith; £2000 to the Leeds General Infirmary to endow two beds; £1000 each to the Cookridge Convalescent Hospital, and to the National Children's Home and Orphanage (Dr. Stephenson's).—The following legacies and donations have been received by St. Mary's Hospitals, Manchester: Women's Guild of Service, £2500; the executors of the late Mr. J. D. Mitchell, £211; of the late Miss R. Hibbert, £150; of the late Selina Greaves, £100; and of Dickanson's Charity, £78.—The subscriptions to the Manchester Cancer Research Fund now stand at £8032, the latest donations being £250 from the Fine Cotton Spinners, and £100 from the Amalgamated Association of Operative Cotton Spinners and Twiners.—Mr. Frank Lloyd, of Sittingbourne Paper Mills, has given a donation of £10,000 to St. Bartholomew's Hospital, Rochester, Extension Fund.

years in which the principal facts ascertained regarding the occurrence of this disease and the manner of its spread have been set out. Efforts are being made in conjunction with the Medical Research Council to add to our knowledge of the causes of this disease and the possibilities of avoiding it.

# Medical News.

University of Oxford.—The Board of Faculty of Medicine has coöpted E. Farquhar Buzzard, D.M., Magdalen College, and Malcolm H. MacKeith, D.M., Fellow of Magdalen College, as members of the Board for two years. The Francis Gotch Memorial Prize in Physiology for 1925 has been awarded to Joyce Wright, B.A., Somerville College. Proxime accessit: Jack Wynne Pugh, B.A., University College.

University of Cambridge.—At recent examinations the following candidates were successful:—

Third Examination for Medical and Surgical Degrees.

*Part I., Surgery, Midwifery, and Gynæcology.*—A. R. Adderley, D. Aserman, G. W. Bamber, J. O. W. Bland, G. C. W. Brown, J. A. S. Brown, P. R. Buckton, G. P. Chandler, P. F. Chandler, H. A. Clegg, L. C. Cook, W. F. Cooper, R. Cunningham, T. S. Dewey, H. V. Dicks, J. Dookray, C. E. Donaldson, A. B. Eddowes, J. B. Ellison, A. W. Ewing, T. D. W. Fryer, S. J. P. Gray, J. C. P. Grey, W. S. Grove, H. J. Heathcote, J. D. Hindley-Smith, G. G. Holmes, J. H. Humphris, I. A. Jackson, D. McI. Johnson, S. Levy Simpson, A. V. Mackenzie, Hon. W. S. Maclay, R. D. Milford, H. L. Milles, W. J. Moody, R. T. Mummery, H. P. Nelson, H. E. Nourse, F. B. Parsons, W. R. H. Pooler, J. D. Procter, L. A. Richardson, R. Riley, J. B. W. Roberton, M. E. D. Roberts, F. C. Roles, G. L. F. Rowell, H. Scudamore, C. J. L. Sharp, G. Simon, R. E. Smith, A. W. Spence, G. M. Tanner, B. C. Tate, G. K. Taylor, H. B. Trumper, J. G. Wigley, H. L. Wilson, R. M. Windeyer, F. G. Winterton, A. T. Worthington, and H. R. Youngman.

*Part II., Physic, Pathology, and Pharmacology.*—D. Aserman, G. W. Bamber, W. A. Barnes, I. C. P. Beauchamp, J. A. S. Brown, Hon. C. B. Buckley, N. F. C. Burgess, R. T. Chadwick, H. A. Clegg, A. C. Copley, R. W. Cuningham, G. H. Day, G. W. S. de Jersey, J. H. Gibbens, N. T. Glynn, R. F. Guymer, C. C. Halliwell, J. C. Hogg, A. T. Howell, W. S. Hunt, J. W. W. Jepps, D. F. Lawson, G. A. Q. Lennane, L. J. Panting, W. R. H. Pooler, R. L. Rhodes, F. R. Sandford, E. M. Shackel, A. Simpson-Smith, H. B. Stallard, E. J. E. Topham, E. A. Trim, J. L. Warner, and H. M. Woodman.

University of London.—At the recent examination for the degree of Master of Surgery John Basil Hume, of St. Bartholomew's Hospital, was approved by the examiners.

University of Durham.—At the Convocation held on Dec. 19th the following degrees and diplomas were conferred:—

Master of Surgery.

James Whillis and Angus H. Whyte.

Bachelor of Medicine and Bachelor of Surgery.

Norman Davison, James W. Dickinson, Basil A. Dormer, Alan Gray, Louis Lavine, Richard A. Pallister, Ernest P. Pratt, Winifred M. Proctor, William S. Walton, and James Y. Woodhouse.

Bachelor of Hygiene.

Ian M. McLachlan.

Diploma in Public Health.

Ian M. McLachlan.

University of Liverpool.—At examinations held recently the following candidates were successful:—

Degree of M.D.

F. S. Fowweather, W. D. Jeans, R. J. Minnitt, M. Newman, and C. Voigt.

Degrees of M.B. and Ch.B. (Honours).

*Class I.*—C. A. Birch (distinction in Medicine and Obstetrics).

Final Examination for Degrees of M.B., Ch.B.

*Part III.*—A. Ashworth, Ethel Barrow, C. Baxter, E. I. Bieber, P. V. Dillon, F. R. Faux, J. H. Gilchrist, R. I. Greenshields, J. Hatton, Enid M. Hughes, T. S. L. Jones, Rebecca Katz, B. Kay (distinction in Obstetrics), Alice M. Luck, D. D. O. McLoughlin, Lilian W. Massey, J. Morrissey, E. R. S. Owen, W. J. Pierce, Thirza Redman, D. Roberts, F. B. Shevlin, P. Strelitz, J. Tarshish, J. E. C. Walker, and W. L. Webb.

*Part I.*—A. B. Anderson, J. H. Boultbee, W. S. Brindle (with distinction), A. N. Cameron, J. K. Cameron, E. Cohen, W. S. Creer, A. Dodd, W. J. Eastwood, K. Edmundson, Elsie A. Griffiths, I. Gurland, E. D. Irvine, R. N. Johnson, O. V. Jones, Theresa J. Lee, J. L. Lewis, F. E. Lomas, J. McHugh, S. G. Massey-Lynch, J. W. Pickup, A. D. Polonsky, C. Rigby, N. W. Riley, G. L. Roberts, Alfreda H. Slater, V. J. M. Taylor, J. P. Thomas, S. L. Tunnicliffe, D. P. de Villiers, E. N. Wardle (with distinction), P. H. Whitaker, and R. L. Wynne.

*Part II.*—Grace A. Austin, W. A. Davies, J. Halton, W. E. Hargreaves, S. P. Meadows (distinction in Forensic Medicine), J. Morgan, J. N. Parrington, E. S. Smith, and Joan Watkins.

Second Examination for Degrees of M.B., Ch.B.

*Part A.*—S. Alstead, E. T. Bates, *R. K. Bowes, S. Canter, J. H. St. B. Crosby, *T. B. Davie, Ariel R. S. Deacon, †T. L. Dowell, R. Doyle, H. R. Dugdale, J. H. Follows, R. A. Furniss, Agnes G. Gillespie, R. G. Gornall, J. J. Graham, G. T. Harris, E. W. Jones, Mary G. Jones, W. E. J. Jones, †T. Lasker, N. R. Lawrie, J. M. Leggate, H. Leiper, C. T. Mercer, Doris Morrison, H. Paterson, Elizabeth B. Robson, E. L. Rubin, †M. Silverstone, H. W. Smith, G. A. Talwrn-Jones, G. G. Warburton, and F. J. Welton.

* Distinction in Anatomy and Physiology. † Distinction in Physiology.

*Part B.*—S. W. Adler, Gladys A. Coventry, A. Dale, R. E. Jackson, K. Jilani, I. Kossow, T. C. Newman, G. W. Phillips, E. E. Prebble, and A. L. Williams.

Diploma in Tropical Medicine.

A. R. D. Adams, F. R. Ashton, Esther Ashworth, C. W. Bamford, J. Beinashowitz, G. Clark, B. A. Coghlan, Ivy Collier, P. G. Cumming, M. Fisher, M. S. Grutu, A. J. Hawe, Z. H. Jafri, Elvy I. Johnstone, J. R. Kerr, D. M. Mackay, M. M. el Mukkawi, L. G. Maldonado, S. F. Mar, B. P. Mozoomdar, D. A. Shan, E. R. Stone, C. G. Terrell, and F. Tooth.

Recommended for Milne medals: Dr. Adams and Dr. Hawe.

University of Birmingham.—At a Congregation held recently the following degrees were conferred:—

*Doctor of Medicine.*—Mabel Thorburn Johnstone, Horace Simkin Savage.

*Bachelor of Medicine and Bachelor of Surgery.*—Dennis Murray Bladon, Zaki Ahmed Goma, Constance Rougier La Trobe, Margaret Elizabeth Lovett, Dorothy May Payton.

The fee for the course, which is strictly limited to 10 members, will be £7 7s. A copy of the syllabus and full particulars may be obtained from the Secretary at the hospital, Westmoreland-street, London, W. 1.

**DENTAL BOARD OF THE UNITED KINGDOM.**—The fourth and last of the series of post-graduate lectures, illustrated by lantern slides, on General Anæsthesia, arranged by this Board will be delivered by Prof. Noel Paton, F.R.S., on the Metabolic Changes in Chloroform Poisoning, at the following places: In London, at the house of the Royal Society of Medicine, 1, Wimpole-street, W., at 8.30 P.M., on Jan. 11th; in Manchester, at the Medical School, University Buildings, Oxford-road, at 5.30 P.M., on Jan. 13th; and in Edinburgh, in the Surgery Theatre of the University, at 5 P.M., on Jan. 15th. The course is intended primarily for dentists and medical practitioners. Dental students are invited to attend. Tickets of admission are not required. It is the intention of the Board to publish these lectures in volume form early this year.

MESSRS. J. and A. Churchill announce that they are publishing this week a new work entitled "The Nematode Parasites of Vertebrates," by Dr. Warrington Yorke, professor of parasitology, University of Liverpool, and the Liverpool School of Tropical Medicine, and Dr. P. A. Maplestone, lecturer in the same school. About 600 figures will illustrate the work, and the object of the authors has been to provide a reliable guide to the allocation of parasites to their genera. A fourth edition of Prof. E. H. Starling's "Principles of Human Physiology" is also to be issued. It has been thoroughly revised and now contains 570 illustrations, 10 of which are in colour. "Recent Advances in Obstetrics and Gynæcology," by Mr. Aleck W. Bourne, obstetric surgeon, St. Mary's Hospital, is now ready.

MR. Lionel de Rothschild has become President of the Hospital for Diseases of the Throat, Golden-square.

**COVENTRY HOSPITAL SATURDAY FUND.**—The Hospital Saturday collection in Coventry this year produced £22,625, and a hospital carnival yielded £3100 in addition.

**LONG WAITING LISTS.**—At the annual meeting of the Edinburgh Royal Infirmary Samaritan Society it was stated that on Dec. 1st last there were 2229 persons on the waiting list of the infirmary, and that two deaths had occurred on account of the delay in admission. At the Leeds Infirmary there is a waiting list of 1700.

**METROPOLITAN HOSPITAL SUNDAY FUND.**—At a meeting of the Metropolitan Hospital Sunday Fund, held recently at the London Mansion House under the presidency of the Lord Mayor, Sir William Pryke, June 27th was fixed as the date on which the annual collection will take place this year. The sum collected on Hospital Sunday in 1925 was £94,841, the fourth highest on record. £84,020 were distributed among 227 institutions. Of the total collections 10 per cent. was appropriated to nursing homes and the purchase of surgical appliances.

**INSTITUTE OF PSYCHO-ANALYSIS.**—The following courses of lectures will be given to medical practitioners and medical students at the Examination Hall, Queen-square, W.C., on Friday evenings at 8.30 P.M., starting on Jan. 15th. The first three lectures on the Unconscious will be given by Mr. J. C. Flugel. Dr. Ernest Jones will then give six lectures on the Theory of Sexuality, to be followed by six lectures by Dr. James Glover on the Psycho-pathology of Anxiety States, Phobias, and Obsessions. Further particulars can be obtained from Dr. John Rickman, 26, Devonshire-place, W. 1.

**CENTRAL ASSOCIATION FOR MENTAL WELFARE.**—A course of eight medical lectures on Mental Disorders and their Early Treatment will be given in the Lecture Hall of the Six Point Group, 92, Victoria-street, S.W., on Wednesdays, at 5.30 P.M., beginning on Jan. 6th. The lectures are intended especially for social workers interested in mental welfare. Dr. T. Beaton will deliver the first lecture, entitled the Nature of Mental Disorder and its Relation to Insanity, and the two following ones on Psychology. Dr. E. Mapother will give two lectures on Clinical Types of Mental Disorder and one on Methods of Treatment of Mental Disorders. The final lectures of the course, on Delinquency in Children and Methods of Investigation, will be given by Dr. E. A. Hamilton Pearson. Further particulars may be obtained from the Hon. Secretary of the Association at 24, Buckingham Palace-road, London, S.W. 1.

**DONATIONS AND BEQUESTS.**—Mrs. Mary Anne Traill, formerly of Brighton, bequeathed £500 to the Royal Sailors' Rest, Portsmouth; £300 to John Groom's Crippleage and Flower Girls' Mission; £200 each to St. Dunstan's Hostel for the Blind, the Cripples' Home for Girls, Marylebone-road, the East London Hospital for Children, the Royal Surgical Aid Society, and the Boy Scouts' Fund; and £100 each to the Hospital for Women, Soho, the Royal Ophthalmic Society, City-road, and St. Mark's Hospital, City-road.—An appeal by the Mayor of Birkenhead on behalf of the local hospitals has reached £1500. In addition a collection made at Cammell Lairds yards on the occasion of the launch of H.M.S. *Rodney* amounted to £310.—The late Mr. T. R. Bolitho left by will, in addition to other bequests, £200 to the West Cornwall Infirmary; £100 each to the Liskeard Cottage Hospital; the Edward Main Hospital, St. Ives; the Miners' Hospital, Redruth; the Helston Dispensary; the Royal Cornwall Sailors' Home and Infirmary, Falmouth; the Royal Cornwall Infirmary, Truro; the Penzance branch of the Charity Organisation Society, and the Penzance Rescue and Preventive Society.—Mr. Hugh Shearwin Hemsley, of Hornsea, formerly of Headingley, Leeds, among other bequests, gave £3000 to the Wesleyan Methodist Foreign Missionary Society, as to £1250 thereof to be for medical missions connected therewith; £2000 to the Leeds General Infirmary to endow two beds; £1000 each to the Cockeridge Convalescent Hospital, and to the National Children's Home and Orphanage (Dr. Stephenson's).—The following legacies and donations have been received by St. Mary's Hospitals, Manchester: Women's Guild of Service, £2500; the executors of the late Mr. J. D. Mitchell, £214; of the late Miss R. Hibbert, £180; of the late Selina Greaves, £100; and of Dickanson's Charity, £78.—The subscriptions to the Manchester Cancer Research Fund now stand at £8052, the latest donations being £250 from the Fine Cotton Spinners, and £100 from the Amalgamated Association of Operative Cotton Spinners and Twiners.—Mr. Frank Lloyd, of Sittingbourne Paper Mills, has given a donation of £10,000 to St. Bartholomew's Hospital, Rochester, Extension Fund.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

### ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

**Wednesday, Jan. 6th.**

SURGERY: at 8.30 P.M.
*Discussion:*
The Surgical Treatment of Duodenal Ulcer. Opener: Mr. C. A. Pannett.

**Thursday, Jan. 7th.**

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.
*Specimens:*
The President (Mr. T. G. Stevens): (1) Carneous Mole retained Eighteen Months in Utero. (2) Two Unusual Cases of Ovarian Tumours.
*Short Communication:*
Dr. G. E. Gibberd: A Case of Obstructed Labour due to Conjointed Twins.
*Paper:*
Dr. Wilfred Shaw: Krukenberg Tumours of the Ovaries.

**Friday, Jan. 8th.**

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
*Cases:*
Dr. Douglas Firth: Patent Ductus Arteriosus.
Dr. W. A. Milligan: Lymphangioma.
Dr. Bernard Myers: (1) Hysterical Dysphagia in a Child. (2) Tuberculous Peritonitis in a Child.
Dr. L. S. T. Burrell: Angio-neurotic Œdema.
Mr. R. Maingot: Carcinoma of Thyroid.
Other cases will be shown.
OPHTHALMOLOGY } at 8.30 P.M. (Cases at 8 P.M.)
LARYNGOLOGY }
*Cases:*
Mr. B. T. Lang: (1) Ruptured Optic Nerve. (2) Pigmented Mole of Iris.
Other cases will be shown.
*Discussion:*
Optic Neuritis in its Relation to Sinusitis.
*Speakers:*
Mr. E. D. D. Davis, Dr. Logan Turner, Mr. Stephen Mayou, and Mr. Foster Moore.
A selection of specimens from the Onodi Collection will be on view on Thursday afternoon, Jan. 7th, and on Friday, Jan. 8th.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Jan. 4th, to Saturday, Jan. 9th.—West End Hospital for Nervous Diseases, 73, Welbeck-street, at 5 P.M. Special course on Nervous Diseases. Mon., Dr. Carnegie Dickson: The Pathology of the Cerebro-Spinal Fluid. Tues., Dr. Hildred Carlill: The Reflexes in Health and Disease. Wed., Mr. Lindsay Rea: Methods of Examining the Eye in Diseases of the Nervous System. Thurs., Mr. Laming Evans: Orthopædic Aspects of Nervous Disease. Fri., Sir James Dundas-Grant: The Auditory Apparatus in Nervous Disease. It should be noted that the first demonstration only takes place at the In-patient Department, Gloucester-gate, Regent's Park.—Bethlem Royal Hospital, S.E. Lecture-demonstrations in Psychological Medicine at 11 A.M. Tues., Dr. Porter Phillips: The Diagnosis and Symptomatology of Mental Diseases Sat., Dr. Thomas Beaton: Psycho-neuroses.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURES.

Friday, Jan. 8th (at Whitworth-street West Branch). 4.30 P.M., Dr. W. E. Fothergill: The Development of Vaginal Operations for Genital Prolapse.

# Appointments.

Hampstead General and North-West London Hospital: Brook, C. D. S., M.B., D.P.H. Lond., House Surgeon; Elliott, Mary H., M.B., B.S.Lond., Casualty Surgical Officer.

Liverpool and District Hospital for Diseases of the Heart: Beattie, Prof. J. M., M.D. Edin., Hon. Consulting Bacteriologist; Crawford, A. C., M.B. Liverp., D.T.M., D.P.H., Hon. Assistant Physician; Evans, W. Howel, M.B. Liverp., Hon. Pathologist; Fenn, A. W. B., L.D.S., Hon. Dental Surgeon; Fordyce, A. D., M.D., F.R.C.P.Edin., Hon. Physician, Children's Department; Harris, I., M.D. Konig., L.R.C.P., Hon. Physician; Jones, T. C. L., F.R.C.S. Eng., Hon. Consulting Surgeon; Leathart, P. W., B.Ch. Camb., Hon. Laryngologist; Oram, W. C., M.D.Dub., D.P.H., Hon. Radiographer; Robinson, A. L., M.D.Lond., F.R.C.S.Eng., Hon. Consulting Gynæcologist.

London Lock Hospital: Phillips, S., M.D., F.R.C.P. Lond., Hon Consulting Physician; Lane, J. E., F.R.C.S. Eng., Consulting Surgeon.

# Vacancies.

*For further information refer to the advertisement columns.*

*Ascot, Heatherwood Hospital.*—Res. Asst. M.O. £300.
*Barrow-in-Furness County Borough.*—Asst. M.O.H. and Asst. Tub. O. £600.
*Bedford County Hospital.*—Asst. H.S. At rate of £130.
*Belfast Joint Nursing and Midwives Council, Northern Ireland.*—Examiners.
*Birmingham General Hospital.*—Med. Reg. and Res. M.O. £155.
*Birmingham and Midland Eye Hospital.*—Res. Surg. O. £150.
*Canterbury, Kent and Canterbury Hospital.*—Third Res. M.O. £125.
*County of London Mental Hospital.*—Eighth Asst. M.O. £300.
*Derbyshire Royal Infirmary, Derby.*—Ophth. H.S. £200.
*East Sussex County Mental Hospital, Hellingly, Sussex.*—Pathologist. £500.
*Gordon Hospital, Vauxhall Bridge-road, S.W.*—Anæsthetist. £21.

*Maidstone, West Kent General Hospital.*—H.S. At rate of £220.
*Manchester City Education Committee.*—Asst. Sch. M.O. £600.
*Manchester Hospital for Consumption, &c.*—Res. M.O. £200.
*Metropolitan Asylums Board Infectious Hospitals Service.*—Med. Supt. £900.
*Middlesex Hospital, Mortimer-street, W.*—Two Asst. Radiologists. £100.
*Plymouth, Didworthy Sanatorium, South Brent.*—Res. M.O. £600.
*Royal Free Hospital, Gray's Inn-road, W.C.*—Second H.P.
*Sheffield, South Yorkshire Mental Hospital.*—M.O. £400.
*Singapore College of Medicine, Straits Settlements.*—Prof. of Bio-Chemistry and Prof. of Biology. Each $850–$1000.
*Southport Convalescent Hospital and Sea-Bathing Infirmary.*—Res. Med. Supt. £600.
*Sudan Medical Service.*—Four M.O.'s. £E.720.
*University of London, South Kensington, S.W.*—University Professor of Obstet. Medicine &c. £200.
*Victoria Hospital for Children, Tite-street, Chelsea, S.W.*—H.P. and H.S. Each at rate of £100.
*West London Hospital, Hammersmith-road, W.*—Hon. Obstet. Reg.
*Wolverhampton and Staffordshire Hospital.*—Res. Surg. O. £250.
The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments for Certifying Factory Surgeons: Tunbridge Wells, Kent; Dover, Kent; Loftus, Yorks, N. Riding.

# Births, Marriages, and Deaths.

## BIRTHS.

Elphick.—On Dec. 20th, at the General Lying-in Hospital, Lambeth, the wife of Cyril Henry Elphick, L.D.S., of a son.

Gray.—On Dec. 22nd, at Westerhall, Weymouth, the wife of Adam Gray, M.D., of a daughter (who only survived 48 hours).

Keys.—On Dec. 17th, at Ravello, Ruislip, the wife of Sydney Hudson Keys, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

Reid.—On Dec. 24th, at Burntwood, Lichfield, Staffs, the wife of Dr. William Reid, of a son.

Wotherspoon.—On Christmas Eve, at Lewisham High-road, St. John's, S.E., the wife of Dr. John Wotherspoon, of a son.

## MARRIAGES.

Powell—McCullagh.—On Dec. 23rd, at University-road Methodist Church, Belfast, Abraham Thomas Watkin Powell, M.C., M.B., D.P.H., of Bury St. Edmunds, to Dorothy Mary McCullagh, L.R.C.P. Edin., L.D.S.

## DEATHS.

Lloyd-Owen.—On Christmas night, suddenly, after a shor illness, at Bron-y-Craig, Harlech, David Charles Lloyd-Owen F.R.C.S., J.P., Warwickshire, aged 82.

Maclean.—On Dec. 25th, at Penlee-gardens, Stoke, Plymouth John Cassillis Birkmyre Maclean, Surg. Rear-Admira (retd.).

Nettle.—On Dec. 23rd, at Parade House, Liskeard, Willia Nettle, M.R.C.S., L.S.A., V.D., J.P.

Stephenson.—On Dec. 21st, at Queen Mary's Hospital, Ro hampton, Major John Stephenson, M.C., late R.A.M.C.

Stirling.—On Dec. 27th, at Grange-road, S.E., Charle Stirling, M.B., C.M., aged 79.

Stocks.—On Dec. 19th, R. Woolsey Stocks, M.R.C.S., L.R.C. D.P.H., M.O.H., West Bromwich, aged 43.

Waugh.—On Christmas Day, after a short illness, Hen Dunn Waugh, M.D., of Onslow-gardens, S.W.

Wightman.—On Dec. 19th, John Prest Wightman, M.R.C. L.R.C.P. Lond., of Scalby, near Scarborough.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notice Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## THE HISTORY OF ANTHRAX IN THE WOOL INDUSTRY OF BRADFORD, AND OF ITS CONTROL.[*]

BY F. W. EURICH, M.D. EDIN.,

SENIOR HONORARY PHYSICIAN, ROYAL INFIRMARY, BRADFORD;
PROFESSOR OF FORENSIC MEDICINE, UNIVERSITY OF LEEDS;
AND FORMERLY BACTERIOLOGIST TO THE LATE ANTHRAX
INVESTIGATION BOARD FOR BRADFORD AND DISTRICT.

ON Feb. 27th, 1878, there appeared in the *Bradford Observer* the following letter:—

"Sir,—Within a month three woolsorters have died from blood poisoning contracted in the same shed of the same factory in Manchester-road. Occasional deaths from blood poisoning, through the handling of some foreign wools, may perhaps be inevitable, but the recurrence within so short a time of three such cases seems to suggest either that the wool itself, or the shed in which it was sorted, is specially unwholesome. May I hope for your help to induce manufacturers to remedy all that is remediable in this deadly trade! No doubt the death of a woolsorter means to the manufacturer merely the loss of an easily replaceable hand, but to others it means the loss, never to be replaced, of son, husband, or father. That I have just come from one such desolate home must be my excuse for troubling you with this letter"

This letter served its purpose. In the correspondence that followed it another writer pointed out that a score of men had died at Queensbury, six at Shelf, and in one month three out of nine sorters employed in a certain shed in Manchester-road, Bradford. Since that date the interest of the Bradford public in the anthrax question has never waned. At that time the nature of this "blood poisoning" had, of course, not been recognised, though the operatives themselves, vaguely conscious of its peculiarities, had called it "woolsorters' disease." It was not a new disease at the time of which I speak. The first case appears to have been noted in 1847, soon after the introduction of alpaca and mohair into this part of the country. The medical practitioners had, on the whole, been slow to note the peculiar features of these cases. Dr. Samuel Lodge, sen., had, it is true, investigated one of them, but his investigation had not led him to any hypothesis upon which further researches could be based.

### *Cause of Woolsorters' Disease.*

The letter just quoted, and the feeling roused by it, induced the coroner to order a post-mortem examination, at which Dr. J. H. Bell was present. Looking through his notes, which are in my possession, I find that he has labelled it "Case 7." His interest in woolsorters' disease was therefore not of recent birth. Indeed, he must have had some experience of this class of case, as we find him reading a paper on it before this Society at the March meeting of the same year. It is characterised by evidence of keen observation and careful reasoning—so typical of the man. After outlining the clinical features he discusses the pathology of the condition. He does not think that the disease is due to the inhalation of fibre, dust, and short hairs, for sorters do not appear to suffer more than other workers from cough; employments which are injurious to health from dust cause chronic—not acute—diseases of the lungs; the microscopical structure and chemical analysis of alpaca, camel-, and goat-hair show that they do not vary much from other wools which do not produce these effects; nor does the incidence of the disease appear to depend upon the amount of dust present. He is of the opinion that the disease is caused by the inhalation of a septic poison, but thinks it is a septicæmia caused by the inhalation of germs produced by the decomposition of animal matter. However, Dr Bell did not hold to this opinion long. A casual suggestion from Dr. Eddison, of Leeds, that the splenic fever of sheep and cattle might be the origin of this disease, caused him to review the evidence and to make further tests. By the autumn of 1879 he had satisfied himself that woolsorters' disease is pulmonary anthrax. His passion for accuracy was such that he could not understand that others might be more careless of the truth. This faith led him at times to accept statements without demanding proofs: and this was particularly in evidence when his practical mind turned to methods of prevention.

### *Early Preventive Measures.*

"How," he says in a later communication, "may they be prevented? Since the subject was ventilated a few months ago Messrs. Mitchell Bros. have had dangerous wools passed through hot water previous to their being sorted. No death nor illness of this kind has occurred from sorting wools so prepared. None can occur. The water removes the septic poison and the dust. If water is objectionable simple exposure of the wool to air for 24 hours is sufficient to render it perfectly innocuous."

Even after his discovery of the true nature of woolsorters' disease, he writes in the *Medical Press and Circular* of Dec. 24th, 1879.—

"I have tried for over two years to impress upon employers the necessity of washing or steaming dangerous wools before they are sorted This will *certainly* prevent the disease. They will not do this unless compelled."

That preventive measures could be enforced only by legal enactment he, of course, fully recognised; and as a necessary preliminary to this he asked for an independent inquiry by the Medical Department of the Local Government Board. Had he been supported by the medical profession in Bradford, he might have succeeded earlier, but only a comparatively small number of his colleagues took his view of woolsorters' disease. Many, indeed, still doubted that the disease was a pathological entity. His energetic spirit chafed at the delay. What could he do to hasten an inquiry? He was, however, undaunted and fearless, and his opportunity came in the spring of 1880. On May 5th there died in King-street, White Abbey-road, a sorter named Samuel Firth. He had been employed by Messrs. Mitchell and Shepherd, spinners and manufacturers, of Spring Mill-street, Bradford, in sorting Cape and "average" mohair, and later Van mohair. Dr. Bell, having attended the man, reported the case, adding to the certificate of death, which ascribed death to woolsorters' disease or splenic fever, the following remark: "from his employers' neglect in not having the mohair he was sorting disinfected beforehand." A coroner's inquiry necessarily followed and lasted three days. It was pointed out by the firm "that Dr. Bell had said the previous autumn that 'if Van mohair were washed it *could* not be injurious to the health of the sorters.' Now he appends a remark to his certificate to the effect that the mohair was not disinfected. We have done exactly what he said would be effective." Though his position was considerably weakened by this shifting of his ground, Dr. Bell attained his object. Public feeling was deeply stirred and the coroner's jury found that the sorting of all dry Eastern wool and hair is dangerous to life except under effective precautions, and made certain recommendations:—

1. That before the bale is opened it be steeped in salt water and remain in salt water not less than 12 hours.

2. That after the bale has been in water the necessary time the hair or wool be placed in a sud of hot water, washed, passed through rollers, and again washed in fresh sud of hot water, partly dried, sorted when damp, and as early as possible after washing; that the temperature of the water be 120° F. at least.

3. That the room be well ventilated, the floor swept daily, walls and ceilings once a month, and thoroughly cleaned and the walls whitewashed every six months with lime mixed with carbolic acid; that no wool or hair or other material be stored in the sorting room, no meals be taken in the sorting room nor food kept there.

4. That proper provision be made for sorters to wash in water near the sorting room.

And the jury further recommended that if no statutory law existed to enforce these arrangements means be taken to obtain the same for the United Kingdom with the object of placing the sorting of wool and hair under the control and inspection of the factory inspector. This was forwarded to the sanitary committee of the Bradford Corporation, who thereupon conferred with representatives of the sorters and received a number of resolutions from the employers which agreed in the main with those of the jury, but contained two important additions.

### *Sources of Infection.*

The first of these was an attempt at classification of wool and hair from the point of view of noxiousness. Hitherto Van mohair had received almost all the blame; now the materials were ranged in two classes. All average mohair, Cape mohair, pellton, and alpaca are to be sorted as usual while all Van mohair, camel-hair, and Persian wool are to be considered noxious and dealt with—i.e., steeped before sorting. To this second specially dangerous class there are to be added all damaged wools of whatever kind. I mention these two suggestions as they figure largely in later investigations; sufficient now to say that the relative degree of danger was deduced from the incidence only of anthrax among the sorters, and not from examination of the material, and that no definition of a damaged wool was given, its characteristics being taken as known only, as will appear in the sequel. It will that no mention is made of a precautionary measure which would appear to us to be a very obvious one—viz., the use of fans. This omission was, however, made good as a result of investigations which were carried on more or less independently of each other by three different bodies. (1) The Local Government Board had taken action and had instructed one of its inspectors, Dr. John Spear, to conduct an inquiry. (2) Prof. Greenfield, at that time director of the Brown Institute in London, had been commissioned by the Board of Agriculture to make investigations on its behalf. The importance of the relation of woolsorters' disease to anthrax had just then been emphasised by the occurrence of splenic fever among cattle on a farm at Harden through which the effluent from Harden mills was carried. (3) The third body was the Bradford Medico-Chirurgical Society. In October of 1880 it had appointed 12 of its members as a commission, of which Mr. Meade was chairman and Dr. Goyder secretary, to inquire into the nature of woolsorters' disease. A small subcommittee was appointed to make the necessary laboratory tests, among which were Dr. Bell, Dr. Appleyard, and Dr. Rabagliati. The results of each inquiry were the same. Dr. Bell's discovery was confirmed, and though one or two doubting Thomases remained—e.g., Dr. Tibbits, of Bradford—the identity of woolsorters' disease and anthrax was never again seriously called in question. Henceforth preventive measures and their enforcement engaged the attention of officials, masters, and men. Mr. Spear's report came as somewhat of a cold douche. It certainly had a sobering effect. No washing process which is compatible with the subsequent sorting of wool can give security. No chemical disinfectant has been discovered which will render wool innocuous without damaging it irretrievably; nor can the germs be destroyed except by a temperature so high as to injure the wool fibres. The precautions upon which he would mainly rely are: First, careful separation of fallen fleeces, preferably in the country of export; secondly, scrupulous cleanliness in the sorting rooms and in the persons of the sorters; and thirdly, withdrawal of the dust by fans.

---

[*] Being a paper read before the Bradford Medico-Chirurgical Society on the occasion of the centenary of the Bradford Royal Infirmary.

The Local Government Board must have considered the report not sufficiently strong to enable it to take action; at any rate, no regulations enforceable by law were drawn up, and everything was left to the conscience of employers and to the force of public opinion. The regulations which in Bradford had been the outcome of the suggestions made by the jury in the case of Samuel Firth received the assent of the employers and sorters, and were voluntarily carried into effect by the majority of firms dealing with dangerous wools.

### *Manufacturers and their Critics.*

As cases of anthrax continued to occur with distressing though certainly diminished frequency, a second conference was held in Bradford in 1884 between the sanitary committee and representatives of the manufacturers and woolsorters. After considerable discussion the existing rules were extensively amended. The principal amendations were: (1) That no noxious material, alpaca, peliton, and Indian cashmere (an addition to the list of possibly dangerous hair) shall be opened in the sorting room, but in a place specially set apart for the purpose, separate and distinct from the sorting room, and shall be opened over a fan by a person capable of judging the condition of the material. (2) The sorting room for all classes of mohair, camel-hair, Persian wool, cashmere, and alpaca shall be provided with extracting fans in order that the dust arising from the material being sorted may be drawn downwards and thus prevented from injuring the sorters. The great advance of the rules upon the old lies in the inclusion among dangerous material of all kinds of mohair and of East Indian cashmere, and in the adoption of fans. While these rules—like the old—could not be enforced by law, there was some protection against the wilfully careless employer in the fear that some day a coroner's jury might find him guilty of criminal negligence. The majority of manufacturers did conscientiously try to carry out these measures, not only according to the letter, but according to the spirit of the rules; but a few conscienceless men now and again defied popular sentiment. Indignation would then be voiced in the press. Thus we find in the *Yorkshireman* a parody of verses popular in those days:

I should, were I of hasty turn,
With indignation boil
To think of those who fortunes earn
By letting workman toil
Amid the deadly Van Mohair
When at a little cost and care
Their lives might shielded be.
In Armley I'd offenders shut
To take their pick at oakum—but
It's nought to do with me.

Bell himself was very outspoken, not only against recalcitrant employers, but also against sorters whose supineness he would chide. Thus, in an open letter to sorters, he writes:—

"Is a woolsorter worse than a beast? Said Hodge to the Squire: 'Sir, that hole should be fenced or someone will stray into it and get killed.' Said the Squire to Hodge: 'That's their look out.' Said Hodge to the Squire: 'Your honour has horses: a horse may get in there and be killed.' Said the Squire to Hodge: 'That's a very different matter. If I lose a horse I lose £80; men cost me nothing. Get the hole fenced.' A man is less valuable than a beast according to the Squire. Does any sane man believe that if Van Mohair killed horses instead of men, it would not be thoroughly disinfected? Most certainly it would; but so long as men cost nothing, and horses cost money, the horses will be better cared for than the men. Woolsorters, are you men? Do you consider yourselves of less value than horses? Will you quietly go on being poisoned from day to day, struck down in a few hours with a horrible pestilence, rather than speak out like men, and refuse to touch the abominable stuff till it has been properly cleansed by those whose duty it is to cleanse it."

### *Efficacy of Early Preventive Measures.*

The next 11 years present little that is of interest administratively or historically. If we examine the effects of the regulations upon the incidence of anthrax in those years we find the number of cases greatly diminished, but this diminution is to be noted almost solely among those operatives who come into contact with the unwashed raw materials—e.g., the openers and sorters. In the various stages that follow upon the washing anthrax still occurred not much less often than it did in the olden days. As no further improvement occurred, and as cases of anthrax were being reported from other parts of the country, a Departmental Committee of the Home Office was appointed in 1896 to inquire into the conditions of wool-sorting and other kindred trades, with a view to the control of anthrax. Meanwhile the sorters were becoming restive, for pending its report, factory inspectors, it was alleged, relaxed the pressure which they had hitherto exercised upon employers to carry out the regulations of 1884.

Hence in places where regulations which were not compulsory had previously been applied these had now been allowed to lapse. One firm was accused of sorting inferior mohair without the protection of a fan, and other firms of having alpaca opened without the assistance of opening hurdles. At length in 1897 the report of the Departmental Committee was published and proved a disappointment. While making no additional recommendation of importance, it asserted that "the suggestion of disinfection, promising as it may appear at first sight, does not bear examination. Anything upon such an enormous scale as this industry would require is hopeless." Furthermore, it errs by defect in not taking into consideration the danger to which carders and combers are exposed.

### *Regulations by the Home Office.*

In February, 1897, Dr. Whitelegge, Chief Inspector of Factories, issued the draft of the long-desired new regulations for wool-combing framed by the Home Office, and which when definitely passed by the Home Secretary would have the force of an Act of Parliament. They were criticised severely both by masters and men, who found an able champion in the late Dr. Hime. As medical officer of health he had been largely instrumental in drawing up the Bradford Rules of 1884, and he now riddled the new regulations with all the eloquence and sarcasm at his command.

After a telling enumeration of all the faults of the new rules he proceeds with his indictment as follows: "Our Parliamentary representatives and Sir C. Dilke have endeavoured to influence the Home Secretary in this matter, but in vain. His regulations are to be obeyed and not to be amended. He has, indeed, promised that if future experience, by which, I suppose, is meant the occurrence of deaths from woolsorters' disease, proves the necessity for greater stringency in the regulations, he may then amend them. The *Observer* to-day attributes to the Superintendent Factory Inspector a statement which, if correctly reported, is one of the most remarkable dicta of historic times. He is represented to have said 'a mistake has been made in London—i.e., at the Home Office.' The sorters have vigorously asserted this all along. The Home Office has stolidly maintained it was right, and now the Superintendent Factory Inspector admits that the department he serves has made a mistake. It has made many." Finally the Home Secretary bent to the storm, and in August, 1897, a draft of the new rules was presented, the Home Office having adopted nearly all the suggestions made jointly by the Chamber of Commerce and the Bradford and District Trades and Labour Council. They fixed the minimum requirements of an efficient opening-screen and sorting-board, and in other and minor points amplified the Bradford rules of 1884, which thereby received legal sanction. Further amendments to these rules were issued in December, 1905, and on Jan. 1st, 1909, statutory regulations for the use of East Indian wool came into force.

*(To be concluded.)*

## PUBLIC HEALTH IN TANGANYIKA.

A REPORT by His Britannic Majesty's Government on the administration under mandate of Tanganyika Territory for the year 1924, recently issued by the Colonial Office, explains that the territory in question consists of a portion of the former colony of German East Africa. The total area is 373,500 square miles, including 20,000 of water. The population, according to the census of 1921, comprised 2447 Europeans (of whom 1598 were British subjects), 9411 British Indians, 789 Goans and Portuguese, 4041 Arabs, 352 Baluchis, 380 unclassified non-natives, and 4,107,000 natives. The European population is composed of officials, missionaries, planters, merchants, and employees of business firms and estates, while Indians and Goans find occupation as shopkeepers, clerks, and artisans.

### *Medical Services.*

The shortage of staff continues, but the position in this respect is gradually improving. During the year under review extensions were made to the hospitals at Kigoma, Mwanza, Songea, Tanga, and Mikindani, while plans were prepared for new hospitals at Moshi, Kilosa, and Dodoma. It is necessary at present to confine criminal and other lunatics in ordinary jails; this is most undesirable, and the erection of a central lunatic asylum to accommodate both criminal and civil lunatics is about to be commenced. A small asylum and jail for criminal lepers will also be erected at Dodoma. A substantial increase in the attendance at the different medical stations is reported. There are 34 main stations from which returns have been received showing a total of 21,080 in-patients and 146,010 out-patients, with 971 deaths. The great success incident in the treatment of yaws with bismuth has proved of great value in inducing sufferers from other diseases to apply for treatment, and the increase of attendance has been very largely due to the propaganda which has been instituted in this connexion. Besides the figures given above several thousand natives were treated for minor ailments at the smaller dispensaries in charge of African dispensers and dressers. Medical officers and sub-assistant surgeons are not entitled to fees in respect of advice to, or attendance on, African natives. No charges of any kind are paid by these natives for attendance, medicines, dressings, or maintenance at Government hospitals and dispensaries, whether they are treated as in-patients or out-patients, except in the case of Government employees drawing 100s. a month or more, and of employees of commercial firms, planters, &c. In regard to maternity and child welfare the initiation of any general scheme to deal with this question must be preceded by careful experiment, and any steps taken must be so designed as to secure that the facilities to be afforded will be acceptable to native women. A European nursing sister was attached to the Health Office at Dar-es-Salaam at the end of the year, and one of her duties is to ascertain by personal investigation the attitude of the natives and to endeavour to gain their confidence and to remove any prejudice existing as regards the treatment of maternity cases in hospital. A small maternity home is being provided in Dar-es-Salaam; should it prove popular with native women similar institutions will be erected in other parts of the territory. The missions still continue to do valuable work among the natives. Apart from general diseases, they devote special attention to the treatment of yaws, venereal disease, and leprosy. The general sanitation of the townships has been maintained in a satisfactory condition.

### *Epidemics.*

There were no serious outbreaks of dangerous infectious diseases during 1924. A few cases of plague occurred in the endemic areas in the Dodoma and Mwanza districts. Towards the end of the year what was believed to be a new focus of infection was found in the Mbulu subdistrict of Arusha; this outbreak resulted in 17 deaths. The decrease in the incidence of small-pox during 1921–23 was still more marked last year; 30 cases were notified, with 12 deaths. 101,000 vaccinations were performed. Influenza was responsible for 38 deaths, the number of cases not being known. While there does not appear to be any danger of a widespread epidemic of Rhodesian sleeping sickness, it is probable that competent observers would find numerous foci of infection throughout the very extensive area of the territory infested with the tsetse-fly of the morsitans group. In the Mwanza district, where Rhodesian sleeping sickness was found in 1923, a few fresh cases have been discovered, but where the instructions issued to the native chiefs by the senior commissioner have been complied with the disease appears to be completely under control. Early in the year reports were received that a disease resembling sleeping sickness was present in the neighbourhood of Liwale, a subdistrict of Kilwa. That it was sleeping sickness was confirmed at Dar-es-Salaam. The investigator estimated that less than 20 deaths had occurred during 1923 and early 1924; he found only three positive cases amongst the many hundreds of natives examined during his tour. In August a number of deaths suspected to be due to sleeping sickness were reported from the Ufipa district. A few cases of human trypanosomiasis have been reported from Kigoma and Ujiji on the shores of Lake Tanganyika. The medical officer stationed at Kigoma is investigating the question where these cases became infected, whether in this territory or in those adjoining. It is known that *Glossina palpalis* is common along the lake shore and that sleeping sickness was endemic during the German occupation. Clearings at landing and watering places have been maintained as far as possible and no further cases of sleeping sickness had been reported from the lake area up to the end of the year. The position requires further investigation. Treatment with Bayer 205 and tryparsamide (the latter kindly supplied by Dr. Louise Pearce, of the Rockefeller Institute) has been carried out, but reports on the results achieved have not yet been received. Both tartar emetic and soamin are also being used.

### *Venereal Disease.*

The treatment of venereal disease and yaws has been largely extended by the use of soluble salts of bismuth with most gratifying results. A special venereal diseases clinic was opened in the Bukoba district with the view, if successful in attracting the natives, to its general and systematic adoption later throughout the territory. The number of natives presenting themselves for treatment for syphilis was 2007 in 1923, and 1377 in 1924. The large population and its wide distribution render it almost impossible to ensure that any measures directed towards compulsory treatment could be administered satisfactorily. In these circumstances it is considered best to encourage the natives to present themselves voluntarily for treatment, thus ensuring the reduction of infectivity on a large scale. The improvement in the situation as regards yaws has been material, the number of cases treated in 1924 being 20,741, as compared with 3010 in 1923, 3123 in 1922, 1109 in 1921, and 630 in 1920. It is hoped that a still further increase will be effected in future, the organisation for dealing with the disease having now been elaborated.

### *Climate.*

Climate of the territory varies greatly according to the height above sea-level of the several districts. Roughly, four climatic zones can be distinguished, though even among these there are considerable local variations. In the warm and rather damp coast region, with its adjoining hinterland, conditions are tropical and the average yearly temperature is 78° F. The hot and moderately dry zone between the coast and the central plateau is characterised by low humidity of atmosphere, less rain, and a temperature rather lower. In the hot and dry zone of the central plateau, between 2000 and 4000 feet in height, the prevailing characteristics are low humidity, little rainfall, and a fairly high mean temperature, with great daily and yearly variations, sometimes exceeding 36° F. daily. The heat is dry, but not so trying to the European as the moist and steamy warmth of the coast, whilst nights are invariably cool. In the semi-temperate regions around the slopes of Kilimanjaro and Meru, of the Usambara highlands, the Ufipa plateau, and the mountainous south-western areas (5000 feet to 10,000 feet), frosts occur at the higher altitudes and the nights are cold. These districts enjoy a bracing climate and can alone be considered healthy for Europeans, but prolonged residence in these altitudes is apt to produce nervous strain even though physical fitness is maintained. There are two well-defined rainy seasons annually. Generally speaking, the long rains begin in February or March and last for two or three months, while the short rainy season extends from October to November, but the rainfall is low for a tropical country and droughts are not infrequent.

## A CHEERFUL HOSPITAL MAGAZINE.

THE editorial article in the *St. George's Hospital Gazette* for December remarks on the varied styles of hospital journals. They range from "the Athenæum type"—mainly composed of massive theses on obscure technical points—down to the somewhat ribald magazine written by the students for the students about the staff. To attain a happy mean which will amuse and edify everyone is very difficult indeed; but of the *St. George's Hospital Gazette* it can be said that its production and general plan are excellent. A contributor proposes that the hospital should launch a bold campaign of advertisement on the suffering public, and suggests the slogans: "All dressers wear spats and long white coats—Transfusions are performed with the 'best Blue Blood from Belgravia' (unless otherwise labelled)—Every suture is warranted hand-sewn," as likely to appeal to Londoners. Visitors are to be encouraged by a series of couplets such as: "If your life hangs by a wisp, ring the bell and ask for ——," and "Your appendix is a red 'un? Have it whittled out by ——." Whilst amongst more serious verse the nursery rhyme: "Little boy blue, Dyspnœic too, See how he's ailin'—He needs Digitalin," is an example of several that combine elegance with instruction.

## AN ANATOMICAL BLACKBOARD.

TEACHERS of elementary anatomy have often attempted to bring home to their pupils some of the facts with which they were dealing by the adoption of methods similar to that utilised by Miss G. Ewart in producing her anatomical blackboard.[1] Fixed points or lines, skeletal or other, were used as foundations on which the remaining parts could be built up or surface markings could be worked out. Miss Ewart, however, has combined on one large sheet the main parts of the body in outline, of a size a little larger than natural, so that the teacher has his wants of this sort at his hand. A simple method is employed by which any of the schemes can be brought to the proper level for the purpose. These schemes will probably be found to be very useful for the purposes which their designer had in mind, and can be recommended in these cases as an aid in teaching. They would not be so useful, probably, where more detailed knowledge and acquaintance is required; for such cases there is, curiously enough, too much in each chart, as, for instance, where the sterno-mastoid is indicated in the neck. Again, in this class, the whole bone is not wanted for surface marking, but only those parts that approach and can be definitely recognised from the surface. The conditions are different, however, among the students for whom these charts are primarily meant, and for these they should prove an agreeable aid.

## COPPER IN PEAS.

WHEN attempting to judge the innocence or harmfulness of the practice of adding small quantities of copper sulphate to brighten the colour of canned peas, we may expect to turn to the physiologist for information on two essential aspects of the question—namely, whether the combined copper of the vegetables can be liberated to a dialysable form by the ordinary digestive ferments, and whether experimental animals will absorb and excrete such liberated copper. Dr. J. C. Drummond has made a study of these two questions (*The Analyst*, 1925, l., 481) and his views, without much experimental detail, were given in a preliminary note read at a recent meeting of the Society of Public Analysts. The preservation of the green colour of vegetables on the addition of copper salts is largely due to the formation of a complex with chlorophyll, phyllocyanate of copper. The amount of copper necessary to preserve the vivid natural colour depends on the amount of chlorophyll present; an average of 50 mg. of copper per kilo is sufficient for most green vegetables. If a greater quantity of copper than this is added to the vegetables the excess of copper passes into combination with proteins from which it is certainly set free during digestion with pepsin and trypsin. On the other hand, it has often been asserted that the copper compound of chlorophyll (phyllocyanate of copper) is unattacked by the ordinary digestive juices of the mammalian alimentary tract, so that the metal is excreted without absorption. Dr. Drummond has shown that this distinction between ordinary protein compounds and chlorophyll compounds of copper is a false one, for copper is liberated in a dialysable form after digestion of the chlorophyll compound of copper with pepsin and trypsin. He investigated this question by in vitro and in vivo experiments. The first series of experiments were carried out by digesting peas in collodion thimbles surrounded by a circulating current of water, and these proved that copper was liberated in a dialysable form during digestion. This conclusion was confirmed by a series of experiments on dogs with Pavlov gastric fistulæ. To determine whether the absorption of small amounts of copper is detrimental, Dr. Drummond fed a group of rats on diets containing approximately one-third of their weight in the form of peas, both normal and greened. The rats on greened peas ingested approximately 1·5 mg. of copper daily per 100 g. weight of rat. The animals lived contentedly on this diet, and it is said that records of the animals' weights showed that the groups fed on coloured peas maintained an identical rate of growth with those fed on the ordinary peas. Post-mortems were carried out, and microscopic sections cut at the end of the tests failed to reveal any abnormality of kidneys or liver. We are not given sufficient details of these experiments to judge of their value as evidence, but presumably Dr. Drummond intends to give a fuller account of his work elsewhere, in which he will cite the number of animals used in the tests, the time they lasted, and the weight curves of the animals. In the meantime we may quote Dr. Drummond's final sentence: "The experiments on rats recorded in this paper make it questionable whether it has yet been proved that the absorption of small traces of copper over long periods of time is likely to lead to harmful consequences."

## MEDICAL MISSIONARIES.

IN the current number of *Conquest and Healing*, the organ of the Medical Missionary Association of London, it is stated that there are at present 463 medical missionaries holding British degrees or diplomas in the mission field, and of these 181 are women. The Church Missionary Society heads the list with 79. The United Free Church of Scotland comes next with 69, while third and fourth are the Wesleyan Missions with a total of 13, and the London Missionary Society with 33. The spring course of lectures under the auspices of the Board of Study for the Preparation of Missionaries will be held at the School of Oriental Studies, Finsbury-circus, London, E.C., beginning on Jan. 14th. Another course of lectures for women missionaries on Moral Hygiene in the Mission Field will be given by Miss J. E. Higson, Warden of the Josephine Butler Memorial House, Liverpool, at the S.P.G. House, 15, Tufton-street, Westminster, on Jan. 18th, 19th, and 20th. Full information as to these lectures can be had from the secretary, Board of Study, 2, Eaton Gate, S.W. 1.

## A MEDICAL CALENDAR.

WE have received a copy of the eighth medical art calendar, published by J. Philip Kruseman, Noordeinde, The Hague, Holland. The calendar, which is well produced, contains about 27 photogravure reproductions of pictures of medical interest. These are mainly Dutch, and include Rembrandt's picture of Tobias operating under the instruction of the angel, and works by Gerard Dou, the younger Teniers, and many others. Two weeks are allowed for the contemplation of each, and whilst all of them might not be received with acclamation in every part of the home, they form a suitable adornment to the doctor's room and may encourage his belief in the progress of medical methods. The price of the calendar is 6*s.*

## LIVINGSTONE COLLEGE.

BY the death of its founder and first principal, Dr. Charles Forbes Harford, the College has lost its most generous benefactor. The need of training in hygiene and elementary medical principles for missionaries out of the reach of skilled advice and in charge of ignorant people is a need which he saw clearly, and to meet it he withstood the opposition which arose when he put his ideas into practice and founded the Livingstone College to provide the necessary training. Students at the College now learn something of the practice of medicine and surgery and get a good grounding in preventive work in hygiene as applied tropical conditions. A number of physicians and surgeo give their services as lecturers, and clinical demonstratio are given at several hospitals; students may enter for full course lasting nine months or may come for shorte periods, from one month upwards. During the year total of 55, of various denominations, received instruction 42 also entered for short courses on the care of health in the tropics. The accommodation of the College is strained to the uttermost, and although it just manages to carry on with its present income, it would be able to do better work if more funds could be found and necessary repairs and improvements could be put in hand. The continued, and if possible increased, help of its supporters is asked in order that current expenses may be met, and, in addition, an attempt is being made to raise £3500 as a memorial to Dr. Harford. Subscriptions may be sent to the Treasurer, Livingstone College, Leyton, London, E. 10.

# An Address

ON

# LIFE ASSURANCE MEDICINE:

## ITS PROGRESS AND ITS LIMITATIONS.

*Read to the Assurance Medical Society on Jan. 6th, 1926,*

BY OTTO MAY, M.D. CAMB., M.R.C.P. LOND.,
PRESIDENT OF THE SOCIETY; PRINCIPAL MEDICAL OFFICER, PRUDENTIAL ASSURANCE COMPANY.

MY predecessor in the chair, Dr. G. G. Howitt, in his extremely interesting presidential address, reminded us how, almost imperceptibly, medical men came to be associated with the business of life assurance. Their first appearance was in the capacity that we now speak of as the "private medical attendant"; later arose the "medical directors," and still later, the actual examiners. In the early days of their association, the function of the examiners, broadly speaking, was to protect the company from the risk of adverse selection—to ensure that the proposers represented, as regards health, an average "cross-section" of the community. Later, however, it was gradually realised that life assurance could be placed on a broader basis than this, that it could be extended to cover lives impaired to almost any extent, provided that there was some prospect of survival for a reasonable period. Consequently upon this widening of the portals the responsibilities of the medical examiner became increasingly heavier. It was no longer a question merely of advising acceptance or rejection of a proposal; it involved, in the case of an "impaired life," the investigation of the nature and extent of the impairment, and, as a corollary, the attempt to estimate the effects of the impairment on the prospects of longevity.

The rapid advance, real or apparent, during the last 30 years in clinical, and particularly in laboratory, methods for the investigation of bodily function has resulted in striking changes in our outlook on the significance of various impairments, and I think it is not without interest to discuss in what directions, if at all, we can show any real advance since the foundation of the Society in 1894.

There are some, particularly the more juvenile among us, who are apt to assume that all change is progress, that we are moving forward in a direct line from darkness towards the light, and that each new "discovery" is a milestone on the road to the omniscience to which we all aspire. Would that it were so! But when I look through the early volumes of our transactions, when I see the wealth of clinical knowledge and shrewd judgment displayed in the papers read at those early meetings, I have an uneasy feeling that, in many respects, our progress has been more apparent than real, and that the elaboration of methods has proved by no means an unequivocal blessing.

### LIMITATIONS OF THE LIFE INSURANCE EXAMINATION.

It is perhaps true that, were one able to command for life insurance work all the resources of the modern hospital or clinic, we might well be able to arrive at a better estimate of the proposer's condition than was possible 30 years ago. But life assurance is essentially a business proposition, not an exercise in the niceties of modern laboratory methods. In practice the examination of the proposer is limited by two factors—the extent to which he will submit to the trouble and expenditure of time involved, and the amount of cash outlay which the Company is prepared to sanction for this purpose.

As regards the first of these factors, if the proposer is really anxious to be insured, he will doubtless be ready to fall in with any reasonable suggestions for special methods of investigation; but if, as is so often the case, he is indifferent as to the [illegible] the difficulty of inducing him to submit to such tests as, e.g., that of his sugar-tolerance curve, is obvious.

As regards the second point—the expense of special investigations—it is equally obvious that a company will hesitate to sanction the outlay of several guineas instead of the usual guinea except in the case of proposals for large amounts; in the case of doubtful proposals for smaller sums, they will prefer either to decline it outright or to come to a decision on such information as is contained in the ordinary report. It follows, therefore, that in the large majority of proposals a decision has to be reached on the findings of the ordinary clinical examination, and it is at least arguable that in this respect the modern practitioner is less, rather than more, skilled than his predecessor of 30 years ago—as a result of dependence on laboratory methods, which, in this case, are unavailable.

Having, I trust, disarmed criticism by this tribute to the virtues of the "nineties," and this confession of our own lamentable shortcomings, I may nevertheless, in all humility, suggest that modern methods may be to some extent helpful in our work. And were I asked to specify one particular point in routine examination in which we have really advanced during the period under review, I should unhesitatingly single out the measurement of arterial pressure.

### ARTERIAL PRESSURE.

The introduction of the sphygmometer into clinical medicine has been, in my opinion, one of the few real diagnostic and prognostic advances of recent years. From the point of view of prognosis, I regard it as the most important single item in our scheme of examination, and trust that the time will soon arrive when the measurements of both systolic and diastolic pressure by the auditory method will become an essential part of every life assurance examination.

It is sometimes said that the finger is the best judge of high tension, and that instruments are unnecessary or even misleading. Dr. W. Russell, of Edinburgh, has always maintained that a good deal of the pressure of the armlet may be required to overcome the resistance of a thickened or contracted artery, and that the reading is by so much greater than the real systolic blood pressure. The great majority of workers on this problem have, however, satisfied themselves that any error due to this cause does not exceed 5–10 mm. Hg, an error that is negligible compared with those [illegible] hyperpiesia at the Bath meeting of the B.M.A. It should be noted that they are based only on policies in force 1–4 years; at some future date I hope to be able to supplement this preliminary report by a larger experience extending over a much longer period.

The paper has been recently published[1] so I will refrain from quoting it in any detail; the following table is, however, from our point of view, its essential feature:—

| | M. and F. combined. | M. | F. |
|---|---|---|---|
| 1. S.A.P. not recorded.. .. | 97·1 | 103·3 | 77·2 |
| 2. „ under 140 .. .. | 102·8 | 105·4 | 83·8 |
| 3. „ 141–170.. .. .. | 133·6 | 133·1 | 139·5 |
| 4. „ over 170 .. .. | 219·6 | 255·4 | — |
| 5. „ „ 200 .. .. | 827·5 | — | — |

(The figures represent the ratio of actual to expected deaths in each group, taking the figure 100 as the ratio of actual to expected deaths in our ordinary branch policy holders medically examined at entry over this period, 1920–24.)

These figures offer striking confirmation of the view that high blood pressure is unfavourable to longevity; that the outlook gets rapidly worse when the pressure is over 170, and that at 200 and over the outlook is extremely unfavourable.

The other table of special interest refers to the relation of high pressure (200 and over) to albuminuria in 130 cases:—

| | |
|---|---|
| Albumin absent .. .. .. .. | 71·5 per cent. |
| Trace of albumin .. .. .. .. | 15·4 „ |
| Albumin in appreciable quantity .. .. | 13·1 „ |

### THE FUNCTIONAL EFFICIENCY OF THE HEART.

The other feature in which it seems to me that some progress has been made in routine examination during the last three decades has been the increasing recognition of the importance of tests for myocardial efficiency. In 1897 the late Dr. Theodore Williams read to this Society an excellent paper entitled the Influence of Heart Disease in Life Assurance. If any one of us is inclined still to believe that the real knowledge of the heart and its disorders began only with the introduction of the polygraph and the string galvanometer, I would suggest a perusal of Dr. Williams's paper as an able exposition of the position of cardiac medicine at the end of the nineteenth century. The following brief extract, from a paragraph dealing with "double mitral" disease, has a very modern ring:—

> "The loudness of the murmurs is no index of the danger of the lesion, but everything depends on the condition of the muscular walls. . . ."

Yet, in spite of this clear recognition of the importance of the heart's capacity to contract adequately, the paper contains no hint as to any tests for estimating what we now call the extent of the "field of cardiac response." But though this omission is so striking in the case of Dr. Williams's paper, yet we find the point not altogether ignored in the subsequent discussion. Appropriately enough, it came from the late Sir Thomas (then Dr.) Crosby, one of the soundest and most experienced examiners of his day. His words are as follows:—

> "An excellent plan, and one I have adopted for years and years, to find out the condition of the pulse, is to trot him round the room, to try the pulse also sitting and standing, and after a brisk walk."

So that, even in 1897, the value of an exercise test in life assurance practice was recognised in one quarter at least; it is curious that it took so long to find its way into routine practice; so far as I am aware, I was a pioneer when, in 1913, I introduced an exercise-tolerance test as one of the items in the examination forms used by my Company.

In the same discussion, Dr. C. Y. Biss sounded a note which strikes a very responsive chord in my own heart. He said:—

> "I have thought sometimes, especially in the teachings of hospitals, that it would be better to persuade the students not to begin with the stethoscope, but to begin in some other way—to very carefully find out the size of the heart and very carefully study the character of the pulse before going to the stethoscope. If we followed that rule ourselves these middle-life cases would not be so difficult to us as they sometimes are."

Myself, I would go even further than Dr. Biss; I say, in all seriousness, that it was a bad day for life assurance when the stethoscope was first applied to the heart; that it has done more to confuse the issues between proposer and company than most of us can realise. Conceive, if you can, the enormous number of perfectly good lives rejected, and, what is worse, made unhappy and invalided, by the discovery of a perfectly harmless "murmur"! Conceive, on the other hand, the number of thoroughly bad lives accepted as a result of the examiner's reliance on the method deprecated by Dr. Biss—acceptance of the stethoscope as the practical arbiter of the heart's condition—"no murmur, therefore a good heart." I repeat that, on balance, the harm done, not only to life assurance, but to medicine generally, by the auscultation of the heart, immeasurably outweighs the good. It is true that, in this respect, we are beginning to learn wisdom, but I feel that even now, in spite of the undoubted advances due to the "new school" of cardiology, the stethoscope still looms too large in the perspective of the heart examiner.

### PULSE IRREGULARITIES.

We have, however, I feel, made a more definite advance in the recognition of different types of pulse irregularity, especially in our ability to differentiate that due to premature contractions (extra-systole) from that due to a fibrillating auricle. It is true that, even now, there is some difference of opinion as to the significance of the former, as was made clear to us by Dr. Strickland Goodall's recent paper. But, allowing for this, our ability to diagnose the principal types of irregularity, and our knowledge of their prognostic value, is a real advance for which we owe a great debt to Mackenzie, Lewis, and their fellow-workers.

To sum up, then, I feel that, during the last 30 years, our methods of routine examination have been usefully enriched by (1) the measurement of arterial pressure; (2) the recognition of different types of pulse irregularity; and (3) the estimation of the field of cardiac response by an exercise-tolerance test, in which attention is paid, not only to the variations of pulse-rate, but to the amount of distress and the nature of the sensory symptoms evoked.

### SPECIAL METHODS OF INVESTIGATION.

When we turn to the *special* methods placed at our disposal during this epoch for the estimation of functional efficiency, we are confronted with a large number of methods of undoubted utility, provided that the proposer and the company combine to render their use practicable. Without attempting anything like a complete list, I would mention particularly (1) skiagraphy, especially of the chest and abdomen; (2) the Wassermann test; (3) the electro-cardiograph; (4) tests of renal function; and (5) sugar-tolerance tests by estimation of the blood-sugar.

Time does not permit of even a brief comment on all of these, still less on many others which I have not mentioned, though each of us could prolong the list to an almost indefinite extent. I should like, however, to consider for a few moments the last two on my list—namely, tests of renal function and of sugar tolerance.

### ALBUMINURIA.

A few moments ago I spoke somewhat forcibly of the dis-service done to medicine, and especially to life assurance, by the application of the stethoscope to the heart. To some extent, though less strongly, the same criticism is applicable to the introduction of urinary tests into the routine examination of the individual. Is there any medical adviser to a life office who is not sick and tired of the ever-recurring problem of how to deal with the apparently healthy proposer in whom is found a trace of albuminuria or a trace of glycosuria? The first paper on a special subject read to the Society (May, 1894) was one by the late Dr. Vivian Poore on the Relation of Slight Degrees of Albuminuria to Life Assurance, and the problem there stated has remained with us ever since. It is true that, from time to time, methods have been, and are still being, brought forward to enable us to determine its significance by further urinary tests—the presence or absence of casts and other abnormal constituents, such as bacteria, pus cells and crystals, the nature of the "albumin," whether serum-albumin or globulin or nucleoprotein, their proportion to each other, the diastase content, and so on, but the problem remained unsolved. In recent years a good deal of work has been done on methods designed to estimate the functional capacity of the kidney as an excretory organ, and so to arrive at a knowlege of the extent of its impairment, if any. For medical prognosis, the most useful methods at present seem to be (a) the estimation of the blood-urea and non protein nitrogen, and (b) the urea-concentration test associated in this country with the name of MacLean. With regard to the former, it is held that a urea-content greater than 40 mg. per 100 c.cm. shows definite retention due to renal inefficiency. From the point of view of life assurance, I think that this may be accepted—i.e., that a urea concentration above this figure is evidence of renal impairment; the converse, unfortunately, is not true; the urea figure may be little, if at all, increased in cases of serious kidney disease, thus:—

---

[1] Brit. Med. Jour., 1925, ii., 1166.

> "Little or no retention is found in parenchymatous nephritis until the terminal stages, hence these cases are not usually detected by an examination of the blood nitrogen distribution"[3]

And again:—

> "It has usually been claimed that blood analysis will indicate whether a particular patient is likely to go into uræmia. Although this is true in the great majority of instances, we have seen four cases in one year with typical uræmia and blood-urea contents below 40 mg. per c.cm. The non protein nitrogen content, however, was high in all."[4]

Hence we may conclude that the test is useful in confirming the presence of serious kidney trouble, but not in excluding it.

With regard to the urea-concentration test, its place in life assurance medicine can, in my opinion, be summarised as follows: A proposer whose urine fails to attain a urea concentration of 2 per cent. after the oral administration of 15 g must be regarded as suffering from definite impairment of renal function; if the examination of the urine and the general condition of the proposer suggest the presence of "granular kidney," the attainment of this concentration must be regarded as a favourable sign that the kidney involvement is slight. If the urine examination, on the other hand, suggests the presence of parenchymatous nephritis, the test has no value in assisting to a favourable prognosis, as many cases have been recorded in which the urea concentration was normal in the presence of advanced parenchymatous nephritis. Personally, my experience of this test has been very limited, and I should welcome the views of any member who can speak from a fuller experience As to the other tests of renal function, such as the phenol-sulphol phthalein excretion test, which have been found useful in surgical practice, I have had no experience at all, but I very much doubt whether any of them would find a practical application in our branch of medicine. On the whole, except for a limited help from the urea-concentration test, we do not seem to have made any appreciable progress in the last 20 years in our attempts to assess the risk in cases of albuminuria. The laboratory has afforded us no short cut, the decision still lies with the clinician from a general survey of all the available information germane to the task.

### GLYCOSURIA.

Very different is the position with regard to glycosuria and its assessment. The last 10 years have witnessed a remarkable advance in our knowledge on this subject. In 1914 I read a paper to this Society on the Significance of Temporary Glycosuria. In my paper I stated:—

> "The vast majority of cases of temporary glycosuria connote a temporary hyperglycæmia."

In the discussion, Sir William (then Dr.) Hale-White commented on this statement, that it

> 'may or may not be so, because it is very rare, surely, for a doctor to test the blood in a case of slight glycosuria, and I have often wondered whether some of the cases may not be those in which the glycosuria is presumably due to an abnormal condition of the kidney letting the sugar through"

Thanks to the improvements in the technique of blood-sugar estimation, it is no longer "very rare" for the blood to be examined in cases of glycosuria. The curve of the blood-sugar percentages following the administration of 50 g. of dextrose is now comparatively easily obtained, and is a most valuable help to us in determining the significance of glycosuria. For us it represents a very real advance in our methods, and enables us to replace guesswork by precise knowledge I have availed myself of this test in a good many cases of glycosuria; some of them have been shown to be of undoubted renal origin—an abnormally low threshold—and these have been accepted at ordinary rates, if all other conditions were favourable. Others have been proved to be frank diabetes of slight or grave degree; in a few the result was of doubtful significance, the so-called "lag curve" indicating a delay in the coming into play of the storage mechanism, so that the blood-sugar concentration shows a short temporary rise above the threshold. This is not a suitable occasion for further detail, but in view of the great advances in this subject which have been made in recent years, I think we might well devote a meeting to the reconsideration of the whole subject of glycosuria, including the effect of insulin treatment on the prognosis in diabetes

So much for a sketchy outline of our progress in methods of examination. On the whole, I think it may fairly be said that we have made some definite advances in the period under review, and that there are reasonable hopes of still further advances in the near future But, when all is said and done, there is something in the examination of a proposer which can be neither measured nor weighed, which is beyond the range of clinical instruments or laboratory analysis. I mean the general impression conveyed to an experienced examiner. We all know quite well that the examination may fail to reveal any definite defect—that the replies to the specific questions in the medical report form may all be consistent with perfect health, and yet—— ! We feel, instinctively, but none the less surely, that his prospects of longevity are below par; that what, for want of a better term, we may call his "vitality," is poor Personally, I regard this as one of the most important factors in assessment, but, unfortunately, when the examination is conducted, not at chief office, but by the occasional examiner, it often happens that we lose the benefit of this impression. And the more we elaborate the methods of examination the greater the risk of overlooking this aspect, of "not seeing the wood for the trees." I do not advocate a return to the primitive method of examination by the candidate's appearance before the board of directors, but I do feel strongly that we should never lose sight of the fallibility of most of our tests, and that we should give full weight to the indefinable, but none the less valuable, attribute of "vitality."

### THE ASSESSMENT OF IMPAIRED LIVES.

When we turn from the conduct of the medical examination to the other aspect of our duties—that of assessing the extra risk, if any—we find even less evidence of progress during the period under survey.

---

[3] Recent Advances in Medicine (Beaumont and Dodds), p. 61

[4] Ibid., p. 75.

For all practical purposes our methods remain entirely empirical; we attempt to translate some physical defect into terms of time or money with little to guide us except tradition and a hope that instinct will supply the answer denied to us by knowledge. When we suggest an addition of 5, 10, or 15 years for, say, an otitis media or an old empyema, do we arrive at our decision on any grounds which we could justify in a court of reason? For most of us, assessment implies a compromise between our hopes and our fears—our hopes of protecting the company and our fears of killing the business. Very rarely indeed is it based on any actual knowledge of the effects of the particular impairment on the expectation of life. On more than one occasion papers of great merit on this topic have been read to this Society by some of our more actuarially-minded members. I would mention especially in this connexion one by the late Dr. T. D. Lister, in 1901, on a Graphic Expression of Extra Risk as implied by an Addition of Years, and one by the late Dr. R. Hingston Fox, in 1902, on the Method of making Advances in Impaired Lives.

But the practical result of these, so far as I can gather, has been negligible. Nor is this surprising. Not many of us, I fear, possess the true statistical mind; still fewer of us realise exactly what is involved in the ordinary method of assessment. It would be an excellent discipline for us to try our hands at super-posing on a normal mortality curve our idea of the curve for some particular case which we are attempting to assess.

Consider, for example, the case of a man of 50 with a moderate degree of myocardial damage. For a healthy man aged 50 at entry, according to the O [M] table, the chance of his dying in the first year of assurance is 0·0074; in the tenth year 0·0291; in the twentieth year 0·0617, and so on. How will the myocardial damage affect the graph? An attempt to solve this simple example will make us realise what guess-work our assessments really are. It would be entertaining, if not flattering to our pride, to compare the answers of all our members if set an examination paper on these lines. Yet this is the problem which we implicitly profess to solve whenever we venture to rate up a proposal. This consideration raises in my mind the question—Does it not seem rather futile to go to a considerable trouble to determine the exact degree of impairment of a proposer when the translation of this into assessment rests on so vague and insubstantial a basis?

The fault, if fault there be, does not, however, rest entirely, or even chiefly, with us. Strictly speaking, the doctor should never be called upon to make an assessment; that should be the duty of his colleague the actuary. In actual practice, perhaps, it might best be done, as it frequently is, by the two in consultation. But it will never be placed on a really satisfactory basis until a joint medico-actuarial investigation has been carried out similar to, but on a wider scale than, the American investigation of 1912. It must aim at the production of mortality experiences for all the ordinary impairments, from data large enough to eliminate the fallacies arising from insufficient cases.

My conception of the ideal basis for assessment is somewhat as follows: The medical men, in committee, should draw up a list of all the important defects likely to be encountered in our work. The actuaries should then gradually accumulate the experience of the offices, and in course of time evolve from this material the mortality for these different classes. It might be advisable to subdivide some of the classes into three subclasses—slight, moderate, and severe. In the case, then, of a proposer suffering from one or more of these defects, the essential duty of the medical officer should be that of stating to which class or classes the proposer belongs. The actual assessment would then be made by the actuary from these data.

In this way I believe that assessment might ultimately become more rational and consistent than it is at present; of course, the offices which specialise in making large profits from impaired lives may quite possibly prefer the present method of rating, but that point would hardly affect the argument as to the theoretical advantages of the new method suggested. I realise full well the great difficulties in the way of attainment—the enormous amount of data required and the labour involved. But I see no reason to doubt the possibility of its ultimate achievement, though many presidents will pass this chair before it becomes an accomplished fact.

# FUNCTIONAL OR ORGANIC?

## SOME POINTS OF VIEW.

By C. P. SYMONDS, M.D. OXF., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN FOR NERVOUS DISEASES, GUY'S HOSPITAL.

THE subject of the minor mental disorders, called functional, should engage the interests—both scientific and humane—of practitioners, for it concerns a group of patients whose ills provide many unsolved problems of pathology and causation, while the nature and persistence of their complaints invite, if they do not sometimes exhaust, our sympathy.

### *The Organic Point of View.*

I will introduce my remarks on this point by citing an extract from a letter written to a consultant about one of these cases by her medical man. It describes succinctly the type of illness which I am going to discuss and reads as follows:

> "I want you to send an appointment to a Mrs. X. She belongs to a group all too common in private practice. I am sure some wise man like yourself will find a lesion in the cerebellum one of these days. The balance of judgment and sensation has gone wrong; they live in their pains, kill all their friends off one by one, and still continue to have pains. What happens in the next world after their departure from this I don't know. Lord help me! Will you, please?"

Follows an extract from the consultant's notes a week later:

> "Mrs. X, aged 63, widow, complains that she is always in pain all over; everything she eats turns to acid; she feels cold terribly, never warm; has pains like electric wires and doesn't want to be touched; feels hungry, yet doesn't know what she wants; has no proper sleep because of her pains; finds it hard to keep from crying. She has been like this for nearly eight years, much worse for the last two. Has been a widow 17 years. Husband died of a stroke. Kept home going for children until a few years ago, when they were all out in the world. Now has nothing definite to do. No previous illness, except that she suffered from migraine up till climacteric at 50. Good physical condition—looks 10 years less than her age. Arteries good. Blood pressure 145. No signs of organic disease. Full of grievances and self-pity."

Further extracts from a letter written the same day from consultant to practitioner:

> "As far as I can gather the trouble began several years ago, when she found the task of keeping house too much for her and gave it up. Since then she has been without any object of interest except herself and her sufferings. Her friend, Mrs. Y, tells me that she never goes out, and makes no friends. I strongly advised her in the presence of her friend to find some kind of an object for herself in life—any regular duty which would in time make her feel she was essential to someone or to some organisation. I suggested, for instance, that she might do some visiting in connexion with the church, visit the sick, read to a blind man, anything so long as it takes her outside herself and makes her feel that she is indispensable to someone. [There follow some suggestions for symptomatic treatment and hypnotics. Finally:] So much for my suggestions as to physical treatment, but it is her attitude of mind (not her cerebellum) which is wrong, and that in a woman of 60 is difficult to correct."

At first sight there appears to be a wide divergence of opinion between practitioner and consultant here. The one speaks of a lesion of the brain, the other of an attitude of mind. But are these two views really incompatible? True, the symptoms of the case belong to a class with which we are familiar, and do not in our experience lead to the development of any of the known physical signs of organic nervous lesions, or to any appearance post mortem from which we can discover the brain to have been diseased.

But we must not regard our armoury of physical signs as complete. It is only 25 years since the significance of the extensor plantar response was discovered. And again, the non-existence of demonstrable lesions, even under the microscope, is but negative evidence and takes us no further. It is but a few years since the symptom-picture of paralysis agitans, for instance, was proved in certain cases to have an organic basis in lesions of the basal ganglia and brain stem.

Let us again dip into the consultant's notebooks. This time it is a case sent up to hospital with the following note:

> "Would you please see the bearer, Mr. Z, aged 42. I don't think there is any actual lesion, but he is worrying himself into a state of neurasthenia. He is firmly persuaded that there is 'something wrong with his stomach' and that he needs an operation. I think perhaps the opinion of a consultant might reassure him."

As the patient walks into the examining room the consultant's suspicions are aroused by a certain immobility of the facies and rigidity of carriage. The gait is slow, the arms still and pronated. As the examination proceeds suspicion develops into certainty that the case is one of encephalitis lethargica.

The patient complains chiefly of vague abdominal discomforts described as a constant sensation of fullness, but sometimes of a feeling of nervousness which comes up from the stomach and makes him "all of a tremble" so that legs and arms shake This is especially brought on by worry. He has been working in his shop, but complains of what he calls "depressions"—pains come across the side of his head and things get mixed. There is a tightness on his head so that he cannot concentrate on his work. His legs get tottery and he is afraid to step out. The same feeling sometimes comes up his back and fixes his neck and the back of his head so that he cannot *move right or left*—that is to say, he can move, but only slowly and with difficulty. All these symptoms he himself attributes to a black draught which he took two years ago for constipation and which he is convinced injured his liver and kidneys. This was in February, 1923. After taking the draught he saw everything double for two days, and has never felt the same since. A short time afterwards he developed insomnia, which persisted continuously for many months.

may result from abnormal habits of mind. The discerning psychologist will, of course, admit that underlying all habit formation there must be some physical change, some alteration perhaps in the setting of synaptic junctions. He claims, however, that such changes are themselves the result of mental processes, and that they may be reversed by other mental processes. This may be easily proved in a case of frank hysteria with physical symptoms, such as a paralysed arm. So long as the patient regards the limb as a dead weight he cannot move it; when he has been persuaded to revise his attitude of mind and accept the arm as an active part of himself, for which he must accept control and responsibility, he recovers the use of it.

Equally striking results may be obtained in some other cases of neurosis, in which the disturbance is at a higher level, the symptoms being more obviously of a mental order. For instance, I shall quote in brief the story of a young man who developed a whole series of anxiety symptoms, including a phobia of blushing. On account of his illness he had already been absent from his work for three months. His real trouble proved to be the inability to meet certain sexual difficulties. He had been living away from home for the first time, and found himself exposed to temptations from which he had hitherto been sheltered. Being of a reserved and sensitive disposition he had reacted to these difficulties by endeavouring to shut them out of his mind. Thus he became self-conscious without any real insight into the cause.

As the result of a few common-sense talks he was first enabled to see his problems, then to view them from a new perspective, and finally to revise his whole attitude of mind towards the troubles of sex, realising that he was encountering a *very common difficulty* which he had to meet in the same way as hundreds of others before him—with courage, self-reliance, and self-tolerance. After going back to his work he wrote *a few weeks later: "It really is extraordinary how different the same world can look in so short a time."* He never looked back.

In many adolescent neuroses equally good results can be obtained. In cases of long standing and in older people treatment is less successful. But it may fairly be argued that in these constant use may have determined fixed patterns among the neurones [illegible] examples in neuro-pathology of the selective action of poisons, for instance, diphtheria, lead, alcohol, anterior poliomyelitis. We have even in neuro-syphilis and encephalitis lethargica some indication of a selective action among the higher functions of the brain, resulting in mental symptoms, which in the case of each disease are somewhat characteristic. Clinical experience also teaches us that mental symptoms may occur in a great variety of bacterial intoxications, the kind of mental disorder being very much the same whatever the organism concerned—a state of confusion which may vary in degree from a condition in which there is a sense of being muddled and unable to concentrate to a violent delirium with complete disorientation.

These mental states one may see in puerperal sepsis, in pneumonia, in typhoid fever, and in some febrile conditions of uncertain origin. From such mental illness the patient as a rule makes a complete recovery, indicating that the nerve-cells have merely been put out of action, not destroyed by the poison. Here, in addition to the mental symptoms, we have constitutional disturbance, but it is possible that poisons with a selective action upon the brain-cells may cause mental symptoms without provoking any constitutional reaction. The advocates of this theory look for the causation of the neuroses in focal sepsis of the teeth or tonsils, in latent infections of the renal, respiratory, or alimentary systems, or in errors of diet and metabolism.

Turning to my notebooks for light upon this aspect, I can find only a very few instances in which treatment of focal infection or metabolic error has produced that striking improvement in the mental symptoms which we should expect if these were entirely of toxic origin. There are several cases of early tubercle, but in all of these there is some hint of physical illness into the bargain.

There is a note, for instance, upon a single woman of 20, whose chief complaint was of loss of energy, irritability, and restless nights. She found herself unexpectedly nervous of traffic and jumpy, and her relatives found her rather peevish and difficult. She had what was considered to be a nervous cough, which sometimes made her sick. But she also had anorexia, and her lack of energy was largely physical. She had enlarged glands in the right axilla and neck, and the X ray showed enlarged and calcareous glands at the roots of both lungs. At the time she was working in a city office. After a month's rest out of doors in the country her symptoms had disappeared; she slept well, ate well, and had recovered her mental spirits and equanimity. The glands in the neck were much smaller.

On the other hand, I find many notes of patients complaining of anxiety, depression, and sleeplessness, in which it is recorded that tonsils or teeth had been extracted, vaccines from the stools given, or a special diet prescribed; for a short while the patient thought he was improved, but subsequently relapsed.

### *The Endocrine Point of View.*

Since the discovery that by the oral administration of thyroid extract it is possible to transform certain toad-like caricatures of humanity into alert human beings, the notion has developed that in the group of cases we are considering there may be some defect of internal secretion, or that the balance of the internal secretions is perverted. This idea has resulted in a great deal of empirical treatment. Unfortunately, there is very little scientific proof for the assumptions upon which such treatment has been based.

There are two methods by which it may be proved that a particular illness depends upon lack of an internal secretion. It may be shown that the illness or abnormality is constantly associated with deficiency or hypertrophy of one of the ductless glands, as in Addison's disease, Fröhlich's syndrome, eunuchism, Graves's disease; or the administration of an endocrine extract may be shown to produce a specific effect upon the disorder, as in myxœdema. The examples I have quoted exhaust the list of disorders in which such proof is forthcoming, and leave us still with the bulk of our neurotic cases unexplained. In my notebooks out of 800 consecutive cases of this type, three only proved to be cases of Graves's disease and one of myxœdema. The great majority had at one time or another been treated with various preparations of mixed glands or with thyroid without anything more than transient benefit in a few cases.

The endocrine theory of causation of the neuroses, therefore, though it must be considered tenable and is supported by certain instances such as I have quoted, still lacks proof. It may be that in this direction new methods of investigation will carry us further, but we must be cautious of accepting a theory merely because it is attractive.

### *The Exhaustion Point of View.*

There are those who designate the minor mental disorders which we are discussing under the title nervous exhaustion. What exactly is meant by this it is difficult to say. Unfortunately, the term is widely used without adequate definition. On the one hand, nervous exhaustion may be taken in a causative sense to imply that the symptoms are due to exhaustion of the nerve-cells; on the other hand, it may be interpreted in a symptomatic sense as comprising all those conditions in which undue fatiguability of the nervous functions is the most prominent feature.

In the latter—*symptomatic*—sense the term might perhaps be convenient. In most illnesses, from an attack of influenza to the cachectic state of malignant disease, mental fatiguability may be a conspicuous symptom. But the use of the word exhaustion instead of fatiguability in this connexion is inaccurate and misleading. In the normal person such symptoms of nervous exhaustion lead simply to a craving for rest, and when this is obtained in sufficient quality and quantity the symptoms disappear. Nowhere was this more apparent than in the war; a man could and would work at high pressure for 48 hours or more at a stretch—and indeed maintain his efficiency for such a period. At the end of this time there would be great subjective discomfort and objective irritability, but 12 hours' sleep as a rule would completely restore the mental equilibrium.

Unfortunately, for the argument of those who claim exhaustion as the important *ætiological* factor of the neuroses, the symptoms of the neurotic are not, as a rule, curable by rest. The patient may be sent to bed for a week and obtain a full allowance of sleep without being a whit the better. Indeed, if only the neuroses were really due to exhaustion, how simple the treatment of them would be! We probably should not even be discussing them, for they would not be of sufficient interest to comply with the criterion of scientific importance which I have demanded for my subject.

Actually, there is a group of neurotics in whom nervous exhaustion in the shape of insomnia seems to play an important part, patients in whom sleeplessness has developed as a habit and whose nerve-cells are probably suffering from accumulated fatigue. I say "probably" because there is no certain means of demonstrating fatigue changes in the cells. The proof lies in the results of treatment. Remedy the insomnia, and the symptoms will disappear. But these cases constitute only a very small percentage of the neurotics whom we encounter in practice. Nervous exhaustion, then, in the symptomatic sense means nothing at all; in the causative sense it cannot be proved, save in a small group of cases, to be an important factor in the production of the neuroses.

The "rest cure," nevertheless, remains a popular form of treatment and is often attended by results which, for a while at any rate, appear satisfactory. The reasons for its popularity are not far to seek. In the first place the patient likes it. The vanity of the average male in particular is flattered by the suggestion that his symptoms are due to overwork. There is a touch of the heroic about this which is comforting. Moreover, the "rest cure" means in all probability a respite from the external difficulties with which the patient has been contending, whether these be difficulties of disappointment at work or discord in the home. Naturally, therefore, in most cases the holiday gives relief. But with its ending the old difficulties have to be faced anew, the old symptoms are apt to return, and the patient, having once accepted the idea that overwork is to blame, feels that he is not yet fit to grapple with his problems but needs more rest. Thus, from moment to moment re-entry into the battle of life may be delayed until a habit of nervous invalidism is engendered, which it is difficult to break.

My own experience of the neuroses leads me more and more to the belief that in this way over-emphasis of exhaustion as a cause may do positive harm.

A young man of 18, for instance, consulted me in January, 1923, on account of inability to concentrate. In July, 1921, he had worked hard for an examination which he passed successfully. Thereafter, without any real holiday, he began working for a scholarship, which he duly obtained in September. In October he entered upon a new course of studies, and after a week or two developed the symptoms of which he still complained. He was then taken to see a physician who made the diagnosis of nervous exhaustion, and advised rest until he got better. He came to me three months later because he still felt unfit for his work. I found no organic disease nor any special worries, and accepted the exhaustion hypothesis, advising further rest, which involved staying away from his work for another term. In April I received a letter from his relatives saying, "He cannot yet bring his mind to concentrate upon study. We think it is better that he should wait until next October before resuming work."

I saw him again in August. He was then still not well. On this occasion he disclosed worries about a pain in the left groin which he associated with frequent seminal emissions. This led to a discussion of sex difficulties with more frankness on his part than he had displayed at the first interview. I began to be critical of my original diagnosis, and advised him to start work in October. He did so and got on well. Early in 1923 he came to see me again with a recurrence of his old symptoms, together with insomnia. This time I was determined to adopt a different attitude. I got him to discuss with me for an hour the particular difficulties of the moment—which were mainly work—and his attitude of mind towards them. I then told him as it was a Friday to take the week-end off, and begin work again on the Monday. I also gave him three cachets each containing 7½ gr. of medinal with instructions to have one ready at his bedside each night and to take it if he had any difficulty in getting off to sleep. He wrote a week later: "I am happy to say that I appear to have regained normal health. I had an enjoyable week-end followed by a slight relapse on Monday, the effects of which seem quite to have disappeared. I did not find it necessary to take more than one of the cachets you prescribed."

He came to me again seven months later with the old symptoms—indistinguishable from those of which he first complained. On this occasion again he proved to be worrying over trivial reverses at his work. He had already taken a week's holiday without feeling any better. We talked over his difficulties and I advised him to continue at once his studies for an approaching examination. He wrote four days later, "I am glad to be able to tell you that I am now feeling perfectly well and able to continue with work. I hope this will be the last time I shall trouble you with this matter."

I believe that in this case if we had continued to regard exhaustion as the cause and rest the remedy, we might still have been waiting for recovery, and that if more effective methods of treatment had been employed from the start a valuable year might have been saved.

### *Summary.*

Having considered the subject from several different aspects we are now in a position to review as a whole the probable nature and causation of the neuroses. We have to admit that the mental equilibrium may be upset in the same way by different causes, and that the mental symptoms resulting, for instance, from the toxæmia of early phthisis, may closely resemble on the one hand those caused by encephalitis lethargica, and on the other hand those which depend upon some undigested worry.

We have learned, therefore, the need of careful discrimination in diagnosis. We have to  aware of ascribing any particular mental symptom or group of symptoms to the action of a particular cause. We have to be constantly on the look-out for such causes as organic cerebral disease, latent toxæmia, disturbance of endocrine balance, and exhaustion. Careful examination will usually suffice to exclude these possibilities. Of the remainder it is claimed that there is, as a rule, something more than negative evidence for regarding them as dependent rather upon wrong habits of mind than the simple effect upon the mental processes of external causes.

Our verdict upon the relative importance of mental habit in these cases has a direct bearing upon their treatment. If we accept the psychogenic point of view we shall not be content to prescribe a rest cure, administer glandular compounds, or cultivate vaccines from the stools; nor shall we be obliged to resign ourselves to the notion of an incurable lesion of the brain. On the contrary, we shall endeavour to investigate the psychological factors at work and help the patient so to improve his mental attitude as to make a more satisfactory adjustment to his difficulties. This, doubtless, requires a good deal of courage. When we inform a patient that his symptoms depend upon faulty habits of mind, however tactfully we may put it, we are passing judgment upon him and asking him to accept some responsibility for his illness. Indeed, such acceptance of responsibility is an essential preliminary to successful treatment. Now, neither the average patient nor his friends and relations are willing to accept such responsibility if they can find some other explanation. They would far rather be told that the symptoms are due to overwork, to encephalitis, to toxæmia, or endocrine disorder. This is particularly true of the relatives in the case of children or adolescents whose faulty habits of mind are due to faulty management and control. It is precisely in these cases that happy results may often be obtained by means of psychotherapy combined with alterations in the domestic régime.

The practitioner who has the courage of his opinions and confidence of the family is sometimes in a position to achieve success. Unfortunately, however, to my mind there are those among the elect who, despite the facts which I have placed before you, proclaim wholesale this or that physical theory of causation as proven. Hence a way of escape for the patient who is unwilling to face his difficulties and an additional embarrassment for the practitioner. The patient seeks other advice and is told, perhaps, that the symptoms are due to some hidden toxæmia and that the remedy lies in its discovery and treatment. If other investigations prove negative there are always streptococci in the stools from which vaccines can be prepared. Prognosis may be, and usually is, guarded—for who knows how much permanent damage the toxins may already have done? But anyway the patient's self-respect and that of his relatives is saved. The medical man who offered the first opinion is discredited. And the opportunity for really effective treatment is lost.

I do not mean that all these cases are amenable to psychotherapy. In a great many the offending habit of mind is ineradicable, either because it is deeply rooted in a constitutional tendency or because it has become fixed by age. But I am convinced that many young persons develop into lifelong neurotics who might have been saved by the timely intervention of commonsense psychotherapy in the early stages of the malady.

Let me conclude with a plea for discrimination in the diagnosis, and commonsense and courage in the treatment of these cases, and above all for a healthy scepticism and the avoidance of cant and humbug. There will always be the neurotic who will not trust his doctor and who will refuse advice because it is unpalatable. To such a one the quack will offer —for a consideration—his panacea, and we may comfort ourselves with the reflection that each w probably get what he deserves—and one will ultimat deserve what he gets.

# THE TREATMENT OF DUODENAL ULCER.*

By CHARLES A. PANNETT, M.D. LOND., F.R.C.S. ENG.,

PROFESSOR OF SURGERY, UNIVERSITY OF LONDON, AND SURGEON TO ST. MARY'S HOSPITAL.

THERE can be no shadow of doubt that a large number of patients ill with a duodenal ulcer get perfectly well, and remain so, under proper medical treatment. Equally beyond dispute is the fact that a smaller number who continue to suffer despite the most careful dietetic and medicinal remedial measures obtain relief by a surgical operation. These remarks are concerned with this latter group.

It is clearly impossible to devise and carry out any surgical procedure unless this be based upon some definite conception of the fundamental nature of duodenal ulceration. Of the various hypotheses of the origin and nature of gastric and duodenal ulcer, that which regards it as an infective lesion is the one which explains most satisfactorily the known facts of the disease. I believe gastric ulcer to be due to an infection with some specific organisms not as yet demonstrable, and that invasion of the stomach or duodenal wall takes place from the lumen of the alimentary canal. Conditions favourable to the growth of the organism would appear to occur at some stage in the interaction of the intestinal and gastric, or possibly pyloric, secretions. When the duodenal bulb, contracting in the presence of pyloric relaxation, causes regurgitation of its contents back into the stomach, they pass upwards along the gastric sulcus, the "Magenstrasse" of German authors. Here they meet the gastric secretions, and at some point along the lesser curvature the optimum conditions for the development of a gastric ulcer occur. When duodenal regurgitation fails we know how there is an apparent hyperacidity, and such patients are recognised as being prone to develop a duodenal ulcer. This is because, in the absence of duodenal regurgitation, the predisposing stage of interaction between the two secretions takes place now in the duodenum itself. Such an hypothesis explains the distribution of gastric and duodenal ulcers and is strengthened by the occurrence of gastro-jejunal ulcers. Here again the lesion appears, not as would be expected in the most acid cardiac region of the stomach, but where the gastric and duodenal secretions meet. These facts suggest that one way to induce the healing of a duodenal ulcer is to alter the environment of the organism in the duodenum. This, indeed, is done by gastro-jejunostomy, the most widely practised method of surgical treatment. But pathological observation also shows us that duodenal ulcers, like the corresponding gastric lesion, are very prone to become callous, to be surrounded by much inflammatory infiltration, and to become so rigid and poorly supplied with lymph that there are very great mechanical and physiological obstacles to the healing process. Just as in the stomach excision of ulcers has, in the long run, proved more effectual than gastro-jejunostomy, so it is suggested that excision of ulcers in the duodenum is on theoretical grounds a better method than the indirect.

## *Results of Gastro-jejunostomy.*

Whether such a belief should be put to the test depends upon the results which can be obtained by gastro-jejunostomy. It is here we come upon contentious ground. It is an undoubted truth that very many duodenal ulcers, even callous lesions, will heal after gastro-jejunostomy. There is not agreement, however, on the proportion of cured patients which results. Elsewhere I have set forth the statistics which have been published. Suffice it here to say that some of the greatest authorities—Moynihan, Mayo, Sherren—claim 90 per cent. or more cures. Such great satisfaction with the operation has not been expressed by other surgeons of eminence, more especially those on the continent of Europe, amongst others Finsterer, Haberer, Clairmont, and de Quervain. These latter authorities put the cures down somewhere about 70 per cent. or less. In a small group of patients which I investigated personally, the cures amounted to 69 per cent. Forsyth's interesting researches amongst doctors who, presumably, would receive early and efficient treatment, showed that 58 per cent. remained free from symptoms after gastro-jejunostomy. Lewisohn found that a little more than one-half the patients are cured and that 18 per cent. suffered subsequently from gastro-jejunal ulceration. Smith has found that in 17 per cent. of cases gross hæmorrhages occur after gastro-jejunostomy. Sometimes this bleeding may lead to a fatal result. Very much rarer is the occurrence of perforation after gastro-jejunostomy. Nevertheless this has happened.

It has been suggested that the discrepancy in the statistical results is due to faulty operating, that the poorer results come from gastro-jejunostomy being improperly performed. This explanation does not suffice for the series I reported. In these cases there was no question of faulty technique. It would seem to me that a more probable explanation is that different classes of cases are being dealt with. If a surgeon operates only upon callous and inveterate duodenal ulcers, his results will not be so good as he who operates upon the non-indurated ulcers of the anterior wall of the duodenum and includes them in his statistical results. For instance, I find very few soft ulcers of this kind on the operating table, because they seem to heal by the efficient medical treatment my patients have always received before resorting to surgery. Of 28 resections of the duodenum, in 53·5 per cent. there were anterior and posterior ulcers, in 28·6 per cent. a single ulcer on the pancreatic wall, and in only 17·9 per cent. a single ulcer on the anterior wall. In favour of gastro-jejunostomy we may say that it is an easy operation to do and has a small mortality, but it is not without a measurable risk in the ordinary surgeon's hands. In a small series I reported three deaths after the operation, all of which were due to lung complications. I do not think generally it falls much below 5 per cent. The reported death-rate from a number of clinics is very much higher. The mortality after operation for a jejunal ulcer is high.

## *Partial Duodenectomy.*

Turning to partial duodenectomy we are confronted with a difficult and tedious technical procedure, and very extensive surrounding fibrosis may make resection impossible, as happens, indeed sometimes with a gastric ulcer. The risks of the operation are particularly injury to the bile or pancreatic ducts or the pancreas itself. Yet with care they can be guarded against, so that the mortality of partial duodenectomy need not be high. Amongst the 28 cases of my own there were two deaths, both from broncho-pneumonia. In one patient the common duct was cut across, but implanted into the duodenum. The patient is well.

Finsterer has been able to carry out 71 resections with only a 1·4 per cent. mortality. Whether partial duodenectomy will take the place of gastro-jejunostomy will depend upon (1) the end-results obtained by the operation, (2) the development of a technique which will make the procedure more easily carried out. The last condition, however, is not absolutely essential. We do not yet know the end-results of duodenal resection. Finsterer reports 93·9 per cent. absolute five-year cures amongst 63 cases. De Quervain, a most careful and cautious observer, asserts that resection of the duodenum gives better results than gastro-jejunostomy, but he does not give figures.

Amongst 16 of my cases who have been operated upon sufficiently long for some indication of end-results to be obtained, 10 are absolutely well, 1 eats anything and has such slight symptoms that he can almost be classed as an absolute cure, 2 have each had one attack of indigestion lasting a fortnight only, and in both of them it occurred approximately one year after the resection, 1 man has had treatment by his doctor for hyperchlorhydria symptoms, and 1 man, 10 months after his operation, says he has a return of pain similar to that of his original trouble: the man whom I reported as having sustained an injury to his common duct has lost his indigestion pain completely, but probably he suffers from a mild cholangitis from time to time. He has never lost a day's work from illness since his operation.

---

* Opening contribution to a discussion on the Treatment of Duodenal Ulcers at the Royal Society of Medicine on Jan. 6th, 1926.

These are the first few cases I operated upon by the method. The future alone will show whether partial duodenectomy should be substituted for gastro-jejunostomy and whether any modification in the *method is desirable.* Just as a limited excision of gastric ulcers proved disappointing, so I believe it necessary to resect more than the affected segment of the duodenum and in my later cases I have been removing a part of the pyloric region of the stomach also. Axial union of the stomach to the duodenal stump is the routine and usually practicable. It was done in 25 of 28 cases. The digestive process by this means would seem to be less disturbed than by gastro-jejunostomy.

I am far from recommending the general adoption of partial duodenectomy for duodenal ulcers in the present state of knowledge, but I do insist upon the fact that the results of gastro-jejunostomy are not so satisfactory that there is no need to seek some improvement in the handling of these cases. Partial duodenectomy has proved itself to be a practical procedure without undue risk, and an investigation of its possibilities and results is certainly warranted.

### *Duodenal Hæmorrhage.*

So much for uncomplicated duodenal ulcers. When bleeding occurs it is far more difficult to formulate a policy. In the first place there is a widespread belief that the hæmorrhage from a duodenal ulcer is never fatal. Whilst this is erroneous, the very existence of such a belief is witness to the fact that many patients recover under medical treatment alone. Yet the risk is there and it is by no means negligible. As in any other kind of bleeding, the best treatment theoretically is the direct. But this presents exceedingly great difficulties. Any operation in an exsanguinated patient involves a risk and an intervention should be as limited as possible. Unfortunately, serious bleeding usually proceeds from a branch of the gastro-duodenal artery, which means that the ulcer is situated upon the pancreatic wall or upper border of the duodenum. It is therefore difficult of access for excision, and ligation of the supplying vessels is not possible. Finsterer, indeed, advocates excision of the duodenum for hæmorrhage, but this is a method of treatment not to be lightly decided upon. On the other hand, I do not discard it absolutely as a method of treatment. Very recently I resected with success a callous ulcer stuck on to the pancreas in a man who, shortly before, had had a severe hæmorrhage, so that at the time of operation his blood contained only 54 per cent. of the normal amount of hæmoglobin. It was done without the aid of a blood transfusion, though ordinarily this would seem to be called for. Should removal of the ulcer be deemed too dangerous, opening the duodenum and cauterising the ulcer, followed by gastro-jejunostomy, is worth a trial. Dunhill carried this out with good result in one patient. Nevertheless, hæmorrhage from a duodenal ulcer is of the secondary type and is prone to recur after simple ligation. Should the ulcer fortunately be on the anterior wall, as occasionally happens, excision followed by gastro-jejunostomy is undoubtedly a good procedure. Gastro-jejunostomy alone has been done for duodenal hæmorrhage. It is a most uncertain measure. I have seen two patients die from recurrent hæmorrhage shortly after it. Finally, there are patients who are too ill for any surgical operation to be thought of. Starvation, rectal salines, morphia, and blood transfusion, with defibrinated blood because of the large amount of fibrin ferment present in it, are the measures to be used, and they are often effective. Too frequently the surgeon sees these patients only after repeated hæmorrhages. It would be infinitely better could the decision for or against surgery be taken at the earliest possible moment. The favourable time for intervention may easily be imperceptibly passed, but whether we should make it a rule to operate upon every patient with duodenal hæmorrhage, or await the progress of the case in the hope of spontaneous arrest, is a question which there are not enough observations available at present to decide.

# EMETINE IN THE TREATMENT OF HEPATIC ABSCESS.

BY PHILIP MANSON-BAHR, M.D. CAMB.,
F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES;
AND
R. M. MORRIS, M.B., B.S. LOND.,
HOUSE PHYSICIAN TO THE HOSPITAL.

IT has long been recognised that injections of emetine, when combined with surgical measures in liver abscess, appear to exert a distinct therapeutic effect in promoting the absorption of pus and obliteration of the abscess cavity, and it is generally conceded that in amœbic lesions of the liver this drug is distinctly more efficacious in extirpating the *Entamœba histolytica* than when this parasite invades the bowel wall.

Some authorities, however, go so far as to state that emetine injections are capable of curing amœbic abscess of the liver and bringing about the absorption of pus, even in the absence of surgical interference. For instance, Hodson[1] in recent papers claims that the pus of an extensive amœbic abscess is entirely absorbed after emetine treatment, and that therefore surgical measures should no longer be considered necessary until full doses of emetine have been employed, on the grounds that the analogy between amœbic abscess of the liver, gumma, and tuberculous abscess is a very close one, and that they should therefore be treated on similar medical lines.

A. S. Fry[2] has reported two cases in India in which the disappearance of signs and symptoms of abscess of the liver and apparent restoration to normal health was remarkable after 12 gr. of emetine had been injected. The records quoted are not very convincing, either that the pus was entirely absorbed, or that in fact suppuration of the liver had ever existed. No exploratory operation for the presence of pus appears to have been performed, and the period of observation subsequent to treatment appears to have been too short to obviate the possibility of a relapse taking place at some future period.

### *Clinical Records.*

While employing emetine injections as an adjuvant in the treatment of liver abscess, we are by no means convinced that when given by itself it will cause absorption of the pus and consequent cure of the condition, as illustrated by the following cases:—

CASE 1.—This man is a pensioner who served in India, where he suffered from "pneumonia" and hepatitis in 1919; recurrences of this trouble took place in 1920 and in 1923, and it was found that he had liver abscess for which he was operated by the transpleural route and drained in the usual way. A second abscess occurred almost in the same situation one year afterwards, which was similarly treated, and he received on this occasion emetine injections. Two months subsequent to the second operation he was admitted to the Hospital for Tropical Diseases with symptoms of recurrence of abscess, with pyrexia, night sweats, epigastric pain, definite enlargement of the liver, and signs of involvement of the base of the right lung; *E. histolytica* cysts were found in the fæces and his blood showed a leucocytosis of 16,500. He was treated on purely medicinal lines with emetine injections (7 gr.) and 18 gr. of emetine-bismuth-iodide. After one month's hospital treatment a great diminution in the liver dullness had taken place, leucocytosis had disappeared, together with all signs and symptoms of his illness, and his physical condition had much improved. He had gained over 14 lb. in weight.

---

[1] Hodson, V. S.: The Treatment of Hepatic Abscess with Emetine, Jour. Trop. Med. and Hyg., 1921, xxiv., 108–109; On Emetine in Liver Abscess (correspondence), ibid., 1922, xxv., 64; Amœbic Hepatic Abscess Treated with Emetine Only, THE LANCET, 1924, ii., 1275–1277.

[2] Fry, A. S.: The Spontaneous Absorption of Amœbic Abscess of the Liver under Emetine Therapy, Ind. Med. Gaz., 1924, lix., 488–492.

It was reasonable to suppose on the evidence so far accumulated that the liver abscess, as it undoubtedly was, had been cured by medicinal means, but in this hope we were doomed to disappointment.

His health, after temporary improvement, once more commenced to deteriorate, so that two and a half months after discharge he reported with hyperæsthesia of the right side of the neck and pain in the region of the right shoulder-joint, sufficiently severe to prevent sleep. His other symptoms were similar to those on the previous occasion. X ray examination showed definite doming and fixation of the right half of the diaphragm. A leucocytosis was present as before. On a similar course of treatment the symptoms and signs subsided in an equally satisfactory manner, but after three weeks in hospital it was noted that, in spite of absence of pyrexia, a leucocytosis still persisted. The liver was then aspirated on 30/4/25 by Mr. P. Kilner and two and a quarter pints of thick yellow liver pus were evacuated with ease. Since discharge from hospital he has regained his weight, and for the last four months has remained in good health.

The points of importance about the above case are: the occurrence of liver abscess seven years after date of presumable infection; the recurrence of a third abscess subsequent to two successful operations; the apparent recovery on emetine treatment without aspiration; and the eventual demonstration of a large amount of pus in the patient at *a time when all ascertainable signs and symptoms* of liver abscess had disappeared.

The second case of a similar nature we quote with the kind permission of Dr. G. C. Low:—

CASE 2.—The patient was a Chinaman, who was admitted to hospital in February, 1925, with enormously enlarged and tender liver, pyrexia, a leucocytosis of 28,000, and signs of intoxication. He was immediately placed on emetine treatment (12 gr.) and during this course two pints of pus were aspirated from his liver. General improvement in the patient's condition then took place for the next three weeks, as evidenced by decrease in size of the liver and disappearance of pyrexia. The leucocyte count at the same time fell to normal. A month later the signs of accumulation of pus in the liver and thorax became apparent, so that it was necessary to aspirate, and on this occasion one pint of similar pus was abstracted. Further aspirations took place on three more occasions, a total of eight pints being abstracted, the accumulation of pus resulting in spite of emetine injections (6 gr.). Finally, rib resection was performed, over five pints of fluid being evacuated, and an abscess cavity of 8 in. diameter in the right lobe of the liver revealed. The cavity continued to drain for five days, when death took place. At autopsy a large ragged abscess showing no signs of collapse or cicatrisation of the walls was found.

It is hardly necessary to emphasise the points of this case, but it was conclusively shown that emetine injections did not in any way prevent the reaccumulation of pus in the abscess cavity.

### *Conclusions.*

The purport of this paper is not to be taken as discountenancing the value of emetine in the treatment of liver abscess, but rather as emphasising that it is only to be used as an adjuvant to such a well-established surgical measure as aspiration. The rapid effect of emetine in acute amœbic hepatitis is probably to be ascribed to the action of emetine upon the amœbæ themselves, and the fact that none of these organisms was found in the liver pus after evacuation in the two cases reported may be also attributed to emetine, but there are no grounds for believing that, under ordinary circumstances, the administration of this drug in any way hastens or affects the absorption of pus which has already been formed within the liver.

## TWO CASES OF
## DISEASE OF THE CERVICAL SPINAL CORD.

BY HILDRED CARLILL, M.D. CAMB.,
M.R.C.P. LOND.,
PHYSICIAN TO WESTMINSTER HOSPITAL;
AND
E. ROCK CARLING, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

THE two cases of disease of the cervical spinal cord to which we call attention showed varying degrees of subarachnoid block, as well as other features of much clinical interest.

### *Hypertrophic Cervical Syphilitic Pachymeningitis.*

A caretaker, aged 31, complained in September, 1924, of weakness in the shoulders and aching pain throughout the upper limbs. The left arm was affected more than the right, and he had on the left side "pins and needles" from the shoulder to the tips of the fingers. He felt his weakness most severely when he lifted, for example, a coal scuttle. In spite of treatment by massage he was getting worse. He said that he had contracted syphilis in 1905 and that he had been treated for this for two years. In the past he was in the regular army, and a boxer. He gave no history of trauma to the neck or spine.

He was seen by us early in January, 1925, and admitted to hospital on Jan. 7th. He showed marked winging of both scapulæ when his weight was supported by his extended upper limbs, due to weakness of the serratus magnus and the lower fibres of the trapezius on each side. At rest there was no deformity or visible abnormality, and apart from the scapular winging and a slight droop of the right upper lid there was no clinical evidence of disease. He had no headache. He stood erect, and the movements of his head and spine were properly and painlessly performed. He could actively elevate the upper limbs in a normal manner. There was no intrinsic atrophy or abnormal posture of the hands, and there was no herpes. There was no anæsthesia, dissociated or otherwise, and the reflexes of every variety were healthy. The electrical reactions of the muscles of the shoulder girdle and upper limbs were normal with the exception of the galvanic response in the right serratus magnus, in which A.C.C. was greater than K.C.C. Apart from the slight droop of the right upper lid there was no evidence of affection of the cilio-spinal centre. Pupils and optic discs were healthy.

The lumbar cerebro-spinal fluid was yellow and showed a coagulum. It contained 0·95 per cent. albumin. The fluid from the cisterna magna was colourless and contained 0·025 per cent. albumin. The fluid from both sites gave completely positive tests for syphilis. The condition clearly was active syphilis of the spinal meninges with intensity about the cervical cord, as shown by atrophic palsy of the serrati and lower trapezii (C. segments 3 to 7). In addition there was obstruction in the subarachnoid space. Hypertrophic pachymeningitis was diagnosed and the man was treated energetically with mercury and iodide of potassium. In a few days hiccup (C. segments 3 to 5) commenced and persisted, when he was awake and asleep, during the remainder of his illness. It developed within half an hour after cistern puncture. Weekly intravenous injections of novarsenobillon and fortnightly intrathecal injections of salvarsanised serum were commenced on Jan. 16th and 21st respectively, and the patient continued to take mercury and potassium iodide. On Feb. 6th paraplegia developed and increased rapidly. Sensation was lost up to the level of the second rib (C. segment 4), and urine was retained. The lumbar cerebro-spinal fluid remained yellow and the cistern fluid colourless. Lipiodol was not employed.

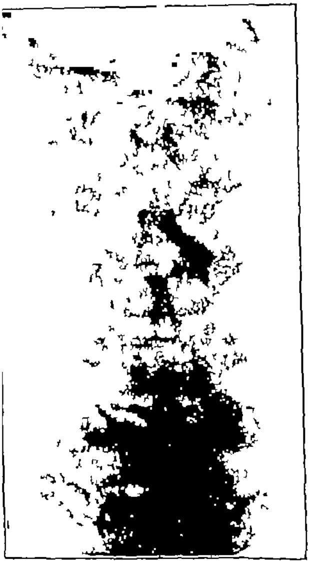
On Feb. 19th, as the severity of the symptoms was increasing in spite of treatment, and threatened an early fatal termination, cervical laminectomy was performed for the purpose of attempting to release the spinal cord from meningeal strangulation. Complete subarachnoid block was found. The meningeal coats were densely adherent to the bone, to each other and to the cord. They were stripped to the limited extent which was possible, but the cord did not pulsate. Although the operation seemed to be very well borne, the man died a few hours later. Autopsy showed the cervical cord encased in thickened, laminated, adherent meninges, and the findings suggested the impracticability of relief by any operation and the probable failure of any medicinal treatment to free the cord from strangulation. The microscope showed marked syphilitic endarteritis, round-celled infiltration and degeneration of the pia-arachnoid, and perivascular round-celled infiltration of the vessels of the dura mater Permission to examine the brain was not obtained.

We call attention (1) to the absence in this case of clinical evidence of internal hydrocephalus as a result of the block in the subarachnoid channel, (2) to the rapid progress of the disease prior to, and therefore not consequent upon, the administration of organic arsenic.

### *Intramedullary Cervical Gliosarcoma*

A woman, aged 41, was seen with Dr H. H. Rubra, of Crouch End, on Feb. 17th, 1925 In August, 1924 she had complained of a sharp pain along the outer part of the left forearm. The pain resisted treatment, but disappeared spontaneously two months later In October, 1924, she developed weakness in the left hand, and in November the right lower limb felt numb so that she failed to appreciate the coldness of a clean sheet with that limb Soon afterwards the left lower limb became weak. During January and February, 1925, she had complained of very severe generalised headache

FIG 1



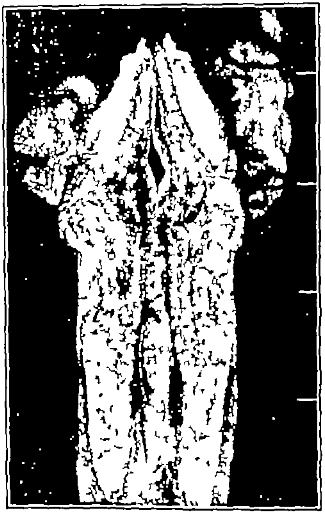
Intramedullary cervical glio-sarcoma part of the lipiodol held up on the right side opposite the fifth cervical spine

*Condition on Examination*—The pupils were healthy The right fundus showed three dioptres of papillœdema, with œdema of the surrounding retina and numerous hæmorrhages on the disc. The physiological cup was not filled The left disc showed slight striation at its upper margin. Atrophy of the intrinsic muscles (Th. segment 1) had produced a griffin hand, and throughout the left lower limb there was paralytic weakness of the upper motor neurone type The right lower limb, though powerful showed early reflex changes of a similar character The epigastric and abdominal reflexes on each side were abolished. The sphincters were healthy Throughout the right lower limb and the lower part of the trunk on the right side there was complete loss of sensibility to pain and temperature Cutaneous sensibility otherwise was nowhere affected

The immediate diagnosis was a lesion, possibly syringomyelia affecting especially the left side of the cervical cord She was admitted to hospital on Feb 23th, 1925 As further examination showed neither deformity of the spine nor any of the features commonly associated with syringomyelia a diagnosis of intramedullary tumour was made The cerebro-spinal fluid from the lumbar region was yellow and contained 0 6 per cent. albumin. The fluid from the cisterna magna was colourless and contained 0 01 per cent. albumin. Tests for syphilis were negative The xanthochromia of the lumbar fluid suggested that the tumour was expanding the cord and causing a subarachnoid block from within. This was confirmed on March 4th by lipiodol injected intrathecally into the cistern, being for the most part held up opposite the fifth cervical spine (Fig 1). The headache was relieved immediately by the lumbar puncture

By March 9th there was increasing weakness of the right lower limb and for three days there had been incontinence of fæces. On the 10th cervical laminectomy was performed to expose the lower four segments, and the clinical, serological and X ray diagnosis confirmed The meninges were not adherent. The cervical cord was uniformly distended and did not pulsate until the meninges were freely incised. When the incision reached the upper limit of the swelling cerebro spinal fluid spurted out. The distended cord was explored with a hypodermic needle with a negative result, and incised on its lateral aspect. This incision was closed by a muscle graft. Shreds withdrawn by the needle were found under the microscope to show sarcoma cells. A week later, the 17th, the swelling of the right disc had abated so that it was too slight to measure On the 21st and 23rd the patient had attacks of unconsciousness followed by severe frontal headache On the second occasion this was relieved promptly by cistern puncture On the 31st she was again unconscious for half an hour On April 1st the right pupil and the right palpebral aperture were seen to be slightly larger than the left

FIG 2.



Intramedullary glio-sarcoma expanding the cervical cord, the longitudinal body in the middle of the lower part of the figure is the spinal cord folded back from below Inches are indicated on the right.

*On the 9th* the lumbar cerebro spinal fluid was found to be far less yellow than formerly and to contain now 0 35 per cent. albumin. There was no swelling of either disc, but in the right fundus there were two small hæmorrhages. The patient had a bilateral infective parotitis.

Between April 7th and 15th patient was much confused and for three days she had recognised nobody Her features were animated and she chattered ceaselessly The lumbar cerebro spinal fluid was under low pressure and now almost colourless. The cistern fluid was under very great pressure and spurted out in a continous stream. Cistern puncture relieved the mental state for a day or two On April 22nd she was again unconscious The eyes floated aimlessly in the orbits and the corneal reflexes were abolished Immediately after a further cistern puncture, at which a fluid of moderately increased pressure was withdrawn, the corneal reflexes were re-established and the eyes moved under her control. On April 30th the patient was drowsy but conscious and her state contrasted greatly with that prior to the last cistern puncture During the examination a divergent squint was observed for the first time On May 1st some exudation was seen around the right disc which was not swollen. The left disc showed slight papillœdema. Death occurred on May 4th. Throughout the illness the temperature was subnormal

At the autopsy the cervical cord, with its cylindrical swelling of tumour, was removed and put aside to be fixed Fig 3 shows its appearance on section. The growth had extended to the brain base There were no deposits elsewhere The brain showed moderate internal hydrocephalus notably of the third ventricle. The intrinsic muscles of both hands were much wasted and the hands clawed

We draw attention to the severity of the headache and the papillœdema *in spite of only a partial block* in the subarachnoid channel, to the diagnosis which was made from the shreds withdrawn by the hypodermic needle, and to the duration of fairly comfortable life due to repeated cistern puncture.

# THE OXYGEN DEFICIENCY THEORY AND EXPERIMENTAL TETANY.

BY J. ARGYLL CAMPBELL, M.D., D.Sc. EDIN.

*(From the National Institute for Medical Research.)*

THERE are many theories regarding the ætiology and pathogenesis of tetany. All of these will not be dealt with in detail here. Recently Critchley [1] and Barker [2] wrote interesting reviews of them, and from these it is clear that, generally speaking, the favoured theories are (1) calcium deficiency, (2) alkalosis, (3) guanidine intoxication. It must be emphasised that both Critchley and Barker are careful to point out that only future research can elucidate the problem, since none of the theories will at present hold for all types of tetany. In the first place, it is difficult to define tetany. It includes mere hyperexcitability of the neuromyone (i.e., nerve-cell and muscle), and all degrees of tremor leading up to typical convulsions; indeed, it is often difficult to determine where tetany ends and convulsions begin. The brain and the spinal cord are the tissues chiefly concerned in tetany and convulsions.

Because of the resemblance of the phenomena in the various types of tetany and convulsions, many attempts have been made to find a cause common to all types both clinical and experimental, and the favourite theories are apparently the three mentioned above.

There is, however, another theory—the oxygen deficiency theory of Morris.[3] He found that there was hyperexcitability of the neuromyone in anoxæmia produced in various ways: that is by asphyxia, decrease of temperature, anæmia, alcohol, and histamine. He studied the oxygen content of the arterial and venous blood, and in that way any change in the oxygen "head" of the blood. Hitherto this theory has not received very great attention. During the past three years I have been studying the oxygen tension in the tissues. Most of my researches have been published in the *Journal of Physiology*.[4] Some of my results give strong support to this theory of Morris. At once it must be admitted that there are still many gaps to fill before the problem may be regarded as settled. Nevertheless, I give the following brief outline and synopsis of the physiological experiments I have so far completed, in the hope that the oxygen deficiency theory may receive the support which it appears to me to deserve.

### *Method.*

A moderate quantity—a few hundred cubic centimetres—of gas, usually nitrogen, was injected under the skin and into the abdominal cavity of an animal and left there until the $CO_2$- and $O_2$-tensions in the gas came into equilibrium with the tensions of these gases in the surrounding tissues. This usually occurred in a few days, the delay being due to the fact that the injection of the gas produced a temporary hyperæmia which required a few days to pass off.

Once constancy had been attained, the tensions remained remarkably constant over long periods of time, until all the gas had been absorbed. It was absorbed very slowly. If 500 c.cm. were injected, some of it still remained at the end of two or three weeks. In this way it was found that the normal $CO_2$-tensions in these situations—i.e., under the skin and in the abdominal cavity—were about 45–50 mm. Hg, whilst the $O_2$-tensions were about 20–30 mm. Hg under the skin and about 30–40 mm. Hg in the abdominal cavity of rabbits and cats. Very similar figures were obtained for monkeys, the only difference that the $O_2$-tension under the skin was similar to that in the abdominal cavity—namely, about 40 mm. Hg. These tensions do not give the tensions inside the cells, but in the fluid and spaces immediately outside the cell wall.

The presence of the gas cannot be considered a normal condition, but no evidence could be obtained that its presence in any way affected the results. It did not matter what gas or mixture of gases—i.e., $O_2$, $N_2$, and $CO_2$—was injected; the final tensions in a few days were always at the same level of constancy for each animal. Nor did the volume, within the wide limits tested, appear to affect the results. Moreover, the evidence obtained by other methods of investigation confirm these figures I have obtained. The tensions remained constant in any one animal for months—i.e., as long as they were under observation.

The method of injection of gas has not hitherto been used to any extent for the study of experimental alterations in tissue gas tensions, simply because the course of events had never been followed out continuously and carefully over days and weeks. The results given previously for tensions in injected gas were most confusing. Most of the observations had been carried out on patients with artificial pneumothorax, many of whom had pathological conditions in the thoracic cavity. Then, again, the thoracic cavity was a most inconvenient position to work with owing to respiration. It was whilst I was working with gas under the skin of normal unanæsthetised animals that the true course of events shown in Figs. 1 and 2 was established. Reference to my previous paper [5] will give full details of the method.

Having thus established a constant base-line for tissue tensions, it was possible to produce tetany and convulsions in an animal and at the same time to draw off samples of gas at intervals and to study changes in $O_2$-tension produced by such experiment.

### *Effect of Experimental Tetany upon the $O_2$-tension in the Tissues.*

In the following description of my experiments I draw no sharp distinction between tetany and convulsions, because it is impossible to separate them.

I produced tetany or convulsions by intravenous injections of guanidine, sodium salts, insulin, water, ammonium salts, cyanides, strychnine, by inspiration of $O_2$ at low tension, and by parathyroidectomy. In order to study the changes of $O_2$-tension in the tissues before the actual onset of tremors or convulsions, it was necessary to delay actual tremors and convulsions for some hours if possible, because muscular contraction itself had a marked effect upon $O_2$-tension, as will be seen later. Tetany was, therefore, induced gradually. In this way it was possible to demonstrate in most cases a marked fall of $O_2$-tension in the tissues—i.e., in the skin and in the abdominal cavity—before the onset of convulsions. Excessive hyperpnœa also markedly lowered the $O_2$-tension and it is a well-known cause of tetany. Alcohol, which sometimes causes tetany, had a similar effect upon $O_2$-tension. So had histamine, which causes increased excitability of the neuromyone [3]; this I include in my definition of tetany.

### *Results.*

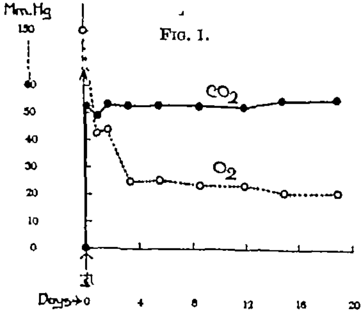
The results are grouped together in the table where I have compared the various theories. A fall of $O_2$-tension before the onset of tetany or convulsions is marked by a positive sign (+). In only three cases of all those tested was this fall of tension absent. These occasions were in cyanide poisoning, strychnine poisoning, and parathyroidectomy. They are very important causes of tetany and convulsions. On further consideration, however, we may remember that in cyanide poisoning the cell behaves as if it were in an atmosphere of nitrogen although oxygen is present; in other words, cyanide poisoning interferes not with the oxygen-supply or oxygen tension outside the cell, but with the intracellular oxidation processes. Now we have no direct proof that this is the case with strychnine or parathyroidectomy, but there is evidence that strychnine convulsions are modified definitely by oxygen administration,[6] the minimal dose being greater when oxygen is administered. That we did not obtain a fall of tissue O$_2$-tension in parathyroidectomy is the weak point in the argument, but there is a probability that there is some similar interference with intracellular oxidation processes as described for cyanide. Many hold that in parathyroidectomy alkalosis is the cause of tetany, and I find that an alkalosis produced by other means—injection of alkali—markedly lowered the O$_2$-tension in the tissues. This fall of O$_2$-tension is considered to be present also in the tissues of the brain and spinal cord which are immediately concerned in tetany and convulsions.

*Table Showing Comparison of Theories.*

| Experimental condition. | Fall of O$_2$-tension in tissues before onset of manifest tetany or convulsions. | Alkalosis. | Guanidine poisoning. | Calcium deficiency. |
|---|---|---|---|---|
| Excessive hyperpnœa | + | + | .. | .. |
| Guanidine injection | + | .. | + | .. |
| NaHCO$_3$ ,, | + | + | .. | .. |
| Na$_2$SO$_4$ ,, | + | .. | .. | ± |
| NaCl ,, | + | .. | .. | ± |
| Insulin ,, | + | .. | .. | .. |
| Histamine ,, | + | .. | .. | .. |
| Alcohol ,, | + | .. | .. | .. |
| Water ,, | + | .. | .. | . |
| Ammonium salts injection | + | ± | .. | . |
| Anoxæmia | + | .. | .. | . |
| Cyanide injection | .. | .. | .. | . |
| Strychnine ,, | .. | .. | .. | . |
| Parathyroidectomy | .. | ∓ | ∓ | + |

It will be seen from my series of observations that the O$_2$-deficiency theory as tested in this way comes out very well when compared with the more popular theories. It will be observed from the table that the guanidine poisoning theory has been supported by evidence from only two of the conditions—i.e., guanidine poisoning itself and in some researches in parathyroidectomy. The alkalosis theory has been supported by the evidence from excessive hyperpnœa, from injection of sodium bicarbonate, and from some observers' results with parathyroidectomy. The calcium deficiency theory is supported strongly by observations in parathyroidectomy [7] and in injections of some sodium salts.[8] This table may be incomplete, but, in so far as I am able to fill in the gaps from experimental evidence, the O$_2$-deficiency theory holds its own easily with the other theories, if there is one and only one common cause for the various types of tetany. This, of course, need not be the case.

FIG. 1.



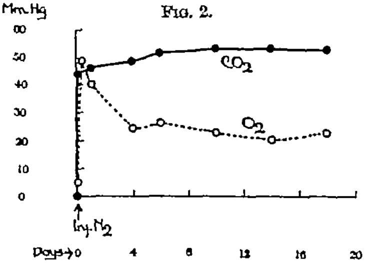
CO$_2$- and O$_2$ tensions in gas under the skin (rabbit) for 20 days following the subcutaneous injection of atmospheric air (*Jour. Physiol.*).

### *Ætiology of Tetany.*

There is yet further evidence in favour of the O$_2$-deficiency theory. When the actual tremors and convulsions developed, the O$_2$-tension in the tissues was markedly improved, on an average by 25 per cent. above normal. It would seem that the purpose of the muscular contraction was to increase the O$_2$-tension in the tissues. I have observed this marked rise of O$_2$-tension following ordinary muscular exercise and in every type of convulsions I have so far studied. These were tremors and convulsions following administration of cyanide, strychnine, insulin, and parathyroidectomy. Not only were the objective phenomena so very much alike in all these types but the O$_2$-tension was equally well raised by all of them.

I have endeavoured to determine how this rise of O$_2$-tension was produced, and found that a marked rise of O$_2$-tension followed production of acidosis by certain doses of such salts as NH$_4$Cl and CaCl$_2$, and also following the injection of certain doses of heart stimulants—e.g., caffeine and ammonia. I have also found that a rise of body temperature produced a slight rise of O$_2$-tension in the skin but not in the abdominal cavity. I have concluded in favour of tissue acidosis as the chief cause of the rise of O$_2$-tension following muscular contraction, the increase of acidity accelerating the liberation of O$_2$ from HbO$_2$. Perhaps, also, it relieves the nerve-cell in its internal oxidation processes in some way. In support of this we have evidence that administration of NH$_4$Cl and CaCl$_2$ are of value in the alleviation of tetany. Administration of O$_2$ is of value in some types of tetany and convulsions but not in others, perhaps because in these cases the cell cannot use O$_2$ although it is there.

FIG. 2.



CO$_2$- and O$_2$-tensions in gas under the skin (rabbit) for 18 days after the subcutaneous injection of nitrogen (*Jour. Physiol.*).

It may be argued why is it that we do not get tetany and convulsions in such cases as fainting. Here, obviously, the heart is weakened; there is a paralytic factor which probably prevents tetany; it is not likely that tetany or convulsions would be of any value if the heart is weak; the heart would not be able to stand it. In a convulsion respiration stops, O$_2$ diminishes and CO$_2$ accumulates for a time, and this itself weakens the heart. Yet in spite of this the O$_2$-tension in the tissues is markedly raised above normal after a convulsion. We also know that the general condition of an animal is often greatly improved by a convulsion—e.g., after insulin convulsions, and after parathyroidectomy, &c.

In clinical tetany the disease seems often to be selective, picking out a group of cells here and a group there. It is in these nerve-cells that we shall have to look for the cause of the disorder.

### *Summary and Conclusions.*

The experiments described support the oxygen deficiency theory of Morris in the ætiology of tetany. It is shown that in many different experimental conditions in which tetany eventually occurs, the tissue $O_2$-tension is markedly decreased before the onset of the tremors. It is shown also that muscular contraction causes a marked increase of $O_2$-tension in the tissues, and it is tentatively suggested that the purpose of the muscular contraction in tremors and convulsions is to supply $O_2$ at increased tension in the tissues.

# Clinical and Laboratory Notes.

## A CASE OF
## ISCHÆMIC NECROSIS OF THE HEART MUSCLE
### SHOWING EVIDENCE OF EMBOLISM ELSEWHERE.

BY GEORGES KLIONSKY, M.B., B.S. LOND., M.R.C.S. ENG.,

RESIDENT MEDICAL OFFICER, WORCESTER GENERAL INFIRMARY.

THE following case of a near relative of mine appears to illustrate well the clinical syndrome described by Dr. A. G. Gibson in THE LANCET of Dec. 19th, 1925, especially in regard to his reference to cases of embolism following the condition :—

The patient, a man of 53, had for some months preceding the attack to be described, complained of præcordial pain, aggravated by exertion, undoubtedly anginal in character. One evening in December, 1924, the pain became more acute and he felt faint, but soon recovered and was up and about the next day. On retiring to bed that evening, he had acute retrosternal pain and lost consciousness. His breathing, from the description given me, would appear to have been stertorous, and his condition was considered very critical. After two or three hours, however, he regained consciousness, but the next evening, when I saw him, he had amaurosis (but said he could see patches of red "resembling roses" in front of him) and he had right internal strabismus. The heart's action was weak, and there were no signs of valvular disease. There was no paresis anywhere else at that time, but he complained of severe headache, especially in the occipital region, and this con- showed multiple hæmorrhages and extensive œdema of both retinæ. The blood pressure was 110 mm. Hg (systolic). No abnormality was detected in the urine. The blood- urea was normal and the Wassermann reaction negative. An X ray photograph of the chest showed slight enlargement of the first part of the aorta. There was no history of rheumatic fever.

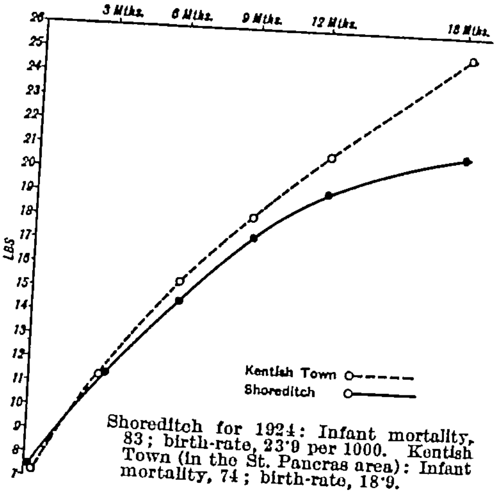
The patient gradually recovered, the retinal œdema slowly disappeared, and the hæmorrhages became absorbed. The strabismus also soon disappeared. At the present day his sight is sufficiently good to enable him to read news- papers and letters, but he still suffers from retrosternal pain, accentuated by exertion.

I think, in view of Dr. Gibson's paper, that the case, clinically at any rate, would appear to illustrate a sequence of events somewhat as follows: Atheroma of the first part of the aorta, with probable involve- ment of the coronary arteries; either thrombosis of a branch of a coronary artery or embolism due to the separation of a small plaque in the aorta; ischæmic necrosis of the heart muscle supplied by that branch; deposition of clot on the inner surface of the heart wall, resulting in the formation of emboli in the brain (one definitely causing the strabismus) and in the retinal arteries (causing the hæmorrhages, with secondary œdema of the retinæ). The case at the time offered considerable difficulty in diagnosis to the medical attendants.

## COMPARATIVE RESULTS IN INFANT WELFARE.

BY AMY HODGSON, M.D., D.P.H. LIVERP., M.R.C.P. LOND.

IT is a common practice to estimate our results in connexion with infant welfare work by means of the infant mortality figure. It has always been assumed that mortality and morbidity go hand in hand. I do not know of any evidence that such is necessarily the case. In the accompanying chart I have contrasted the average weight of a series of children under my care in Kentish Town with another such series in a generally "lower" district—Shoreditch. 300 children in all, attending the clinics fair regularly, enter into the curve shown. It w be seen that the Kentish Town curve corresponds almost exactly with the normal curve of variou authorities (Holt, Pritchard, &c.) that it is difficu to mark both on the chart. The Shoreditch babie were actually larger at birth (7 lb. 6 oz., as agains 7 lb. 3 oz. in Kentish Town), and held their initia advantage until 3 months of age. From tha time there is a gradual falling off, which become more marked from the time the children get on t general food. I may say that a sufficiency of mil was ensured throughout in each case. This wa issued from the centre (usually as dried milk) and actually *given* whenever necessary. When the child was breast-fed, milk was obtained for the mother in necessitous cases. It was found impossible to prolong the curve beyond 18 months, as the attendances became irregular, and the average is taken from too small a number of children.



Shoreditch for 1924: Infant mortality, 83; birth-rate, 23·9 per 1000. Kentish Town (in the St. Pancras area): Infant mortality, 74; birth-rate, 18·9.

I attributed the less good results we were able to obtain in Shoreditch to the accumulated effect of difference in conditions which I observed from the time the children first came up to the clinics in their respective areas. The Kentish Town babies were better off as regards (1) clothing; (2) general standard of mothering—the Shoreditch mothers being definitely more "elementary" in type; for the most part, they were supremely satisfied with their own standards of life; (3) facilities for fresh air and open-air life (Kentish Town is near to Hampstead Heath and to Parliament Hill Fields).

From the point of view of the health authorities, I should say that both areas were efficiently visited. The feeding in both clinics was the same, though, generally speaking, in Shoreditch the directions given were less faithfully observed. The attendances at the centre were less regular in Shoreditch. Housing conditions are bad in both areas. There is no evidence that any of the factors mentioned came into operation before the age of 3 months. Two further factors (of serious import to the Shoreditch babies) come into operation from 6–9 months; (1) The imminence of another baby—the children followed more rapidly one upon the other in the family in Shoreditch. This gives rise very constantly to a falling off in care. (2) The poor quality of general food obtainable for the children.

While a fat or vitamin deficiency was avoided by the free issue of cod-liver oil, there was certainly a deficiency of easily digested protein of good biological value—e.g., egg—in the case of the Shoreditch children. They lived too much upon bread, as the fresh fruit and vegetables ordered could not be afforded them. The mothers did not make broth; many mothers had very little knowledge indeed of cooking, and so were quite unable to make the best of the food available. The Ministry of Health are at present conducting an exhaustive inquiry into the health of children under school age. May we hope that a systematised comparison, on the one hand, between class areas and standards and, on the other hand, between financial conditions operating, will form part of any report on such inquiry?

I am much indebted to the authorities in Shoreditch and Kentish Town for permission to publish these figures.

# Medical Societies.

## SOCIETY OF MEDICAL OFFICERS OF HEALTH.

### FEVER HOSPITAL MEDICAL SERVICE GROUP.

A meeting of this Group was held at the Society's house in London on Dec. 18th last, when Dr. F. H. Thomson, the President, occupied the chair, and Dr. John Churchill Blake, assistant medical officer, N.E. Hospital, M.A.B., read a paper on the

### Schultz-Charlton (Blanch) Reaction[1] in Scarlatina.

In the series to be considered, he said, horse serum only was used. It may be injected into any part of the trunk or limbs provided that the rash is bright and not too coarse; but in most cases in his own series the chest and abdomen were chosen. The dose in all cases was 0·2 c.cm., and a very fine needle should be used in order to avoid deep injection or bleeding, which may obscure the reaction. In tests for diagnostic purposes the dilution should not be higher than 1 in 10, and in his series the percentage of positive results would certainly have been higher if this had been adhered to; but in a large number of cases 1 in 100 was the lowest dilution used. The time before blanching occurs varies from 4 to 5 hours to 30 hours. Where several dilutions are used on one patient the period seems to be longer the higher the dilution; there is a difference of about two hours between 1 in 10 and 1 in 100 and so on. The age of the rash, at any rate during the first three days, does not appear to have much bearing on the time taken for serum to cause blanching, and intervals of 4–6 hours are quite common on the third day. (On the fourth day the period is considerably longer.)

The maximum area in any case, said Dr. Blake, was 1¼ in. in diameter. The size varies with the degree of dilution but not proportionately, being usually ¼ in. between 1 in 10 and 1 in 100. Blanching may be complete or a faint rash may be present, and a central area of apparent inflammation, quite distinct from the redness caused by the puncture of a small vessel, has been observed in several cases. Usually the reaction lasts for at least 24 hours and often until the rash has disappeared. The area gradually increases in size until it attains its maximum, when it either remains stationary or gradually recedes, the rash returning in the blanched area until the site of injection can no longer be recognised.

In the majority of Dr. Blake's cases the test was not used for diagnosis but to provide information by which the blanching titre of the serum could be estimated. With most of the batches used blanching was obtained up to 1 in 500. As the "age" of the rash increased serum injected intradermally became less effective. On the first day (65 cases) the percentage of positive results was 78; the fall in efficiency was gradual up to the third day, and there was a big drop to 37 per cent. (eight cases) on the fourth day. The total percentage of positive results was about 73. Probably the percentage of positive results on the fourth day was higher than it should have been owing to the small number of cases, but blanching can certainly be obtained on the fourth day in some cases, although the rash has usually disappeared before the serum has time to take effect. Where the rash is still bright on the fourth day the reaction is generally negative even with 1 in 10 dilution. In several instances serum was given intramuscularly at the same time or a few hours before the Schultz-Charlton injection, and blanching occurred in all except two cases. This procedure, said Dr. Blake, might prove useful as an indication of the efficacy of the serum, the same serum being used in each case, especially if a second dose was considered advisable.

In order to test the specificity of the reaction it was tried with rashes which were known or suspected not to be due to scarlet fever; in all cases dilutions of 1 in 10 as well as higher dilutions were used. These cases included: One prodromal measles rash, five measles, one prodromal chicken-pox, two rubella, two serum rashes, two food rashes, three cases of erythema, one septic rash. No blanching occurred in any of these cases. Ten patients were injected intradermally with normal horse serum; in one case slight blanching was reported. In addition to the blanching titre, the Schultz-Charlton reaction shows the length of time that serum retains its antitoxic properties. A batch set aside for one month (in refrigerator) and used again gave good results.

*Discussion.*

Dr. R. A. O'Brien, director, Wellcome Physiological Research Laboratories, said that he could not help feeling that the Schultz-Charlton reaction is a measure of what is happening therapeutically. Presumably, therefore, so long as antitoxin can neutralise toxin in the skin, antitoxin will be useful therapeutically, though this is not yet proved. It has been shown that the Schultz-Charlton reaction is effective up to the seventieth hour, but the likelihood of its being positive after that time is small. The general tendency has been for serum, when given in toxic cases, to be efficient up to the third or fourth day, but after that period its efficiency is lessened. Dr. O'Brien considers that much bigger doses than those used by Dr. Blake could be given, and although in the work of his laboratory 0·2 c.cm. was the dose used, it was not clear that they were not losing by so limiting it. It is possible, he said, that by the use of a larger dose the number of positives might be increased. The fact that blanching has been obtained with 1/500 and 1/1000 dilutions is of especial interest. Whether or not that is a measure of the antitoxic value of the serum is a matter open to question. In his own view the method of judging the value of a serum by obtaining passive immunisation of a Dick-positive reactor is a very difficult one to carry out.

Dr. J. E. McCartney, director of Research and Pathological Services, M.A.B., suggested that the Schultz-Charlton reaction might be very useful to determine whether or not there are two distinct types of scarlet fever. Those which gave negative results in Dr. Blake's series might possibly have been cases of a different type of the disease. Special attention should be given to these negative cases.

---

[1] In 1918 W. Schultz and W. Charlton stated that intradermal injection of serum taken from a normal person or from a convalescent case of scarlet fever into the skin of a person suffering from bright scarlet fever rash is followed by blanching of an area around the site of injection. W. Mair has shown that the serum of a normal person does not produce the effect unless he has been immunised against scarlet fever. More recently the serum of horses immunised by means of the hemolytic streptococcus has been used in doses of about 0·2 c.cm. The test has been applied to a number of rashes due to other infections and it is said that no blanching occurs.

Dr. William Mair, research pathologist, M.A.B., said that he has had no difficulty in giving 0·75 c.cm. of undiluted horse serum without causing any appreciable discomfort. Slight discomfort is produced at the beginning of the injection, but as soon as 0·1 c.cm. is given it appears to have a numbing effect on the nerve-endings and no further trouble is experienced. He believes that occasionally horse serum gives the reaction in a very mild degree, and in some cases there is a blanching indicating that there is at times a small amount of natural antitoxin in the normal horse. This is not surprising since the horse is subject to streptococcal affections and also to immunity of some kind. The whole question, added Dr. Mair, is of great interest from the point of view of the ætiology of scarlet fever.

Dr. W. M. Macfarlane, Birmingham City Hospitals, stated that he has used the Schultz-Charlton reaction with very satisfactory results and has also given convalescent serum in many cases. With various sera the reaction usually persisted until the rash faded, whilst with convalescent serum it certainly did so in all cases. The batches of sera varied. In some instances blanching was produced in 18 hours with 1/1000 dilution, and in others in six hours with 1/10 dilution.

Dr. D. MacIntyre, medical superintendent, Plaistow Fever Hospital, said that he has had difficulty in getting 1 c.cm. into the skin. The majority of cases arrive at his hospital after the third day.

The President said that from the clinical point of view he considered the Schultz-Charlton reaction a very promising one. It had helped in diagnosis on several occasions in his own experience, and had been of great value in cases in which there was doubt. He agreed with Dr. O'Brien that it would probably be of advantage to increase the dose, and said that he understood that when Dr. Mair was doing tests with 0·75 c.cm. there had been practically no inconvenience to the patients. Mentioning one or two cases in which the blanching lasted some two days after the rash had gone, he said that this was accounted for by the exceptional whiteness of the skin; no desquamation followed in the particular area that had been blanched. Though this phenomenon did not occur in all cases it might occasionally be encountered.

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF OBSTETRICS.

A meeting of this Section was held on Dec. 18th last, Dr. D. G. Madill, the President, being in the chair.

### *Hyperemesis in Early Pregnancy.*

Dr. Gibbon FitzGibbon, Master of the Rotunda Hospital, read a paper on this subject.

The President said that reflex hyperemesis was understood to be due to some pelvic lesion, but he had not a great deal of faith in reflex hyperemesis, except in cases of erosion which were being treated and in which actual manipulation of the cervix might produce it. Even in non-pregnant cases manipulation of the cervix would produce vomiting if it was continued for long enough. He was not a great believer in neurotic vomiting, as plenty of neurotic patients went through pregnancy without any hyperemesis. Personally, he thought that about 90 per cent. of cases of hyperemesis in early pregnancy were toxic. In cases of reflex or neurotic hyperemesis no such post-mortem lesions in the liver and kidneys were found as were seen in cases of extreme hyperemesis in the later months of pregnancy. Hyperemesis ended at about the end of the fourth month of pregnancy—the time when the action of the trophoblast was most severe—and he was of opinion that if a patient got over the fourth month she would get through all right. In all these cases blood and urinary examinations should be made. In early cases of severe morning sickness he put the patients on a milk diet and purgatives, and every time they drank milk, or even milk and soda, he made them lie down for an hour afterwards; by doing this they were much more likely to retain food. He kept them on this régime for a month, and then if they were better he stopped it; but if they were not better he put them on complete starvation and elimination. He found in these cases that doses of glucose and bicarbonate of soda were effective. Before he emptied the uterus he would try giving the patient corpus luteum extract. If hyperemesis was due to migration of chorionic villi injections of placental extract might help. Obstruction of the bowels was, he thought, a predominant factor in most cases.

### *Neurosis or Toxæmia.*

Dr. L. Cassidy said that he did not agree with the President that obstruction of the bowels was a predominant factor in hyperemesis. If it were so, hyperemesis would surely be much more common, since constipation was very usual in pregnancy. In the case of a girl aged 24, who had vomited continuously for three weeks and was in a very bad state, a rectal enema was given, and sodium bicarbonate, and three bougies were passed without any effect. After this Cæsarean section was done, and the patient never vomited afterwards. In cases of this kind it was rather difficult to put toxæmia out of mind. Acidosis was present in most cases, but this would be found in any case of starvation. He was of opinion that there was a neurotic element in a large number of cases of hyperemesis. He thought that Dr. FitzGibbon's experience of two fatal cases must be unusual, as he had recently read a report on a German authority who had treated thousands of such cases and had had very few deaths. A certain number of women were very desirous of terminating pregnancy and would adopt any means to bring it to an end short of inducing abortion by physical means. Referring to the fact that hyperemesis only occurred up to the fourth month of pregnancy, he said that he thought there was little doubt that a certain number of these cases might be due to inability of the maternal tissues to deal with the products which they contained. It was possible that some dysfunction of the corpus luteum might also be responsible for causing sickness.

### *Importance of Misplacement.*

Dr. J. S. Quin said that he quite agreed with Dr. FitzGibbon about the neurotic element in cases of hyperemesis, and thought that the strongest argument in favour of this was the extraordinary variety of methods of treatment which were brought forward, all of which had good results. In a condition which was cured by so many diverse methods of treatment he thought it was fair to assume that they all acted by suggestion. The essential thing in treating all these patients was to remove them from their immediate surroundings. In these cases he believed that often there was misplacement, and when a patient complained of vomiting the first thing to be done was to make sure that this was not the cause.

Dr. D. Cannon, referring to the fact that hyperemesis was supposed to be due to starvation and dehydration, said that if this were true he did not see what good emptying the uterus would do.

Dr. A. H. Davidson said that recently it had been suggested that blood serum from a normal pregnant woman should be given to women suffering from hyperemesis.

Dr. FitzGibbon, in replying, said that he had no doubt about reflex hyperemesis being present in the early months of pregnancy. Erosion as a cause in such cases was absurd. In nine cases out of ten the cause of the hyperemesis was retroversion. Neurotic vomiting invariably ceased at the fourth month, when the uterus ceased to be a pelvic organ and began to be an abdominal organ. He did not at all advocate emptying of the uterus as a cure for cases of hyperemesis. He believed that the death of one of his patients was due to starvation, which was so far advanced that he could not relieve it. Vomiting in early pregnancy was, he thought, nearly always neurotic. Sometimes hyperemesis was associated with hydatid moles, but in his first two years at the Rotunda Hospital he had had a good many of these cases and did not think that any of them were associated with vomiting of which notice would be taken. Acidosis in these cases was, he believed, the result of tissue wasting, from starvation. His second fatal case was one in which he had induced labour. It was said that chloroform was the cause of tissue or liver degeneration, but he had given both chloroform and ether in toxæmic conditions without any bad effect.

### *Ovarian Dermoid in a Child.*

Dr. CANNON showed an ovarian dermoid removed from a child aged 9 years, which had produced acute vomiting, some fever, and tenderness and rigidity of the lower abdomen. A tumour was felt and a pre-operative diagnosis of ovarian cyst was made. The abdomen was opened, and a tumour found occupying most of the pelvis, the left lobe of which was congested and red. There was no blood-stained fluid and no torsion, and a small pedicle. The other ovary was normal.

The PRESIDENT said that this was a very rare and interesting specimen. It was, he thought, idle to speculate about the origin of dermoids; but it was known that they occurred at all ages and in both sexes, sometimes up to 70 years of age, as well as in unborn children. They were generally painless, but had a great tendency to become malignant, even in young patients. It was interesting to note that one piece of the ovary was left perfectly healthy in the tumour.

Dr. FITZGIBBON said that he had never seen a case of this sort in a child as young as 9 years; the tumour was very large to be found in so young a patient. The combination of a multilocular cyst and the dermoid was very interesting, as it showed that there was another definite pathological growth in the ovary as well as the dermoid.

Dr. CANNON, in replying, drew attention to the similarity between cases of ovarian cyst and of abdominal tuberculosis, and referred to a patient he had recently seen who had been treated for abdominal tuberculosis till breathing became difficult, and at operation had been found to have an ovarian cyst under the liver

## RESPIRATION IN DISEASE.

*Respiratory Function in Disease.* By JONATHAN C. MEAKINS, M.D., C.M. M'Gill, F.R.C.P., F.R.S. Edin., Professor of Medicine, M'Gill University, Physician in Chief to the Royal Victoria Hospital, Montreal; formerly Christison Professor of Therapeutics in the University of Edinburgh; and H. WHITRIDGE DAVIES, M.B., B.S. Adelaide, Lecturer in Methods of Clinical Investigation in the Department of Therapeutics, University of Edinburgh. London and Edinburgh: Oliver and Boyd 1925. Pp. 402. 28*s*.

THIS should become a standard work on respiration in disease. In some ways it may be regarded as the companion to Prof. J. S. Haldane's lectures on Respiration which have been recently published in book form.

After a historical résumé, a section on normal respiratory function gives in a very readable form a short, succinct description of the physiology of respiration, including all the recent work. An account of hæmo-respiratory function in disease, which occupies about half of the book, is especially valuable as it contains not only the authors' views on the various disputed points clearly expressed, but embodies much of their own experimental work as well as that of others. In a chapter on vital capacity in disease the authors hold the same view as some other investigators—viz., that the vital capacity in health shows considerable variations, so that it cannot be safely used as a standard of physical fitness or as a means of diagnosis in individual cases of pulmonary tuberculosis. There is a short chapter on the basal metabolic rate. A further chapter on the therapeutics of respiratory disturbances throws doubt on the action of the ordinary so-called respiratory stimulants. The methods of oxygen administration are clearly described and analyses are given showing the relative advantages of the different methods. Emphasis is laid on the importance of administering $CO_2$ as well as oxygen in the treatment of poisoning by morphia and carbon monoxide. The book is completed with a valuable chapter on methods of investigation. There is an exhaustive bibliography which contains some 400 references.

Such a book, dealing with a subject in which knowledge is advancing almost daily, will certainly require further editions at not too long intervals of time. It is on this account that the following suggestions on matters of detail are made. The authors infer that the radiogram of the heart shows its contour during systole, but surely this is only the case if a carefully timed and momentary exposure is employed. The ordinary ortho-diagram of the heart, taken with an exposure of some seconds, is usually regarded as representing the heart's shadow in diastole. Whilst it is probably true that bronchitis by itself is not a cause of breathlessness, the authors attribute the breathlessness so common in chronic bronchitis to emphysema, though it would seem at least equally likely that coexisting asthma is responsible. The fact that they quote with approval the statement that in emphysema the prolonged expiratory sound is characteristic, suggests that they have neglected the asthmatic element in their cases, for it is usually held that in pure emphysema the breath sounds are diminished and that it is only when asthma is present that the expiration becomes prolonged. The very small section devoted to the blood changes in congenital heart disease might well be further expanded. The authors do not give enough credit to Pembrey and Allen who gave us all our present knowledge of pathological Cheyne-Stokes respiration. Douglas and Haldane repeated their observations on Cheyne-Stokes breathing artificially produced. The headings of the pages have not been varied sufficiently, so that between pp. 92 and 233 it is impossible to find out at a glance what particular hæmo-respiratory function is being dealt with. Finally, in a future edition it would perhaps be better to incorporate the frequent footnotes in the text.

The excellent way in which the data are presented makes it possible for the reader to draw his own conclusions, which is very necessary in a subject developing so rapidly. The work should be useful alike to the advanced student, the research worker, and the general physician, and is thoroughly to be recommended.

---

*Dyspnœa.* Medicine Monographs. Vol. V. By JAMES HOWARD MEANS, Harvard Medical School. London: Baillière, Tindall and Cox; Baltimore: Williams and Wilkins Company. Pp. 108. 11*s*. 6*d*.

PROF. MEANS has written an excellent short account of dyspnœa in the present book. The matter is well arranged and the arguments are clearly expressed. About two-thirds of the book deal with the causes of dyspnœa in disease, which are classified under the headings: Dyspnœa associated primarily with Increased Metabolism; Dyspnœa associated primarily with Disturbance of Acid Base Balance; Dyspnœa associated primarily with Difficulty in Oxygen Transport; and Dyspnœa associated with Mechanical and Nervous Hindrances to the Respiratory Movements. In this section there is a discussion on reduced vital capacity. Then follow sections on cardiac dyspnœa and on dyspnœa in pneumonia. The early part of the book is devoted to the physiological aspect of the subject, whilst the last chapter deals with treatment. There is an excellent bibliography, and the book can be recommended as a short readable account of recent work.

### THREE SURGICAL MONOGRAPHS.

Edited by DEAN LEWIS, A.B., M.D., EUGENE H. POOL, A.B., M.D., and ARTHUR W. ELTING, A.B., M.D. London and New York: D. Appleton and Co. 1925. Each 21*s*.

1. *Peritonitis*. By J. GARLAND SHERRILL, M.D., F.A.C.S., Colonel M.O.R.C., U.S. Army, formerly Professor of Surgery, Kentucky University and also of the University of Louisville. Pp. 397.

THE series of surgical monographs, of which this is one, published under the editorship of three distinguished American surgeons, bids fair to fulfil admirably the objects which the editors have had in view. They have wisely chosen such subjects as visceroptosis and diseases of the spleen, of which the literature, though extensive, is scattered and sometimes difficult of access. A great service has been done by the presentation of comprehensive reviews of these debatable provinces of surgery. Future workers will have not only a basis of knowledge from which to start out, but they will gain from the experience of an authoritative writer. The present volume on peritonitis conforms to the general plan of these monographs, but does not quite reach the high standard of its predecessors. The book is too large for the subject, so that a number of irrelevant matters are dealt with, or at least subjects such as cholecystography and the treatment of uncomplicated gastric ulcers, which have but a slender connexion with peritonitis. On the other hand, when we seek information about Ochsner's method of treatment, or proctoclysis or laparoscopy, we do not find the details which we might expect in a monograph of this size. The author's experience of perforated gastric ulcers is peculiar. He declares that perforation takes place mostly on the posterior wall and that the exudate is more or less limited to the lesser peritoneal sac. He ends by saying "the lesser curvature or the anterior wall may be the site of perforation in a small number of instances." Only nine lines are devoted to the surgical treatment of peritonitis from ruptured gastric ulcer in this section, though the treatment of uncomplicated gastric ulcer occupies nearly three pages. The author is at his best when he speaks of his own experience. He has been impressed with the results of gastric lavage in peritonitis, which have forced him to conclude that much of the toxæmia in grave cases is due to absorption from the lumen of the alimentary canal.

There is much useful information within the covers of this book, and a good bibliography is attached to each chapter.

---

2. *Fractures of the Humerus, Radius, and Ulna.* By E. L. ELIASON, A.B., M.D., ScD., F.A.C.S., Professor of Clinical Surgery in the University of Pennsylvania Medical School. *With the collaboration of* R. GOLDSMITH, M.D., Instructor in Surgery in the same Medical School, and E. P. PENDERGRASS, M.D., Instructor of Radiology, Post-Graduate School of Medicine, University of Pennsylvania. Pp. 307.

THE literature dealing with fractures is already immense, but the vast proportion of it was written prior to the adoption of numerous X ray improvements, and it is principally for this reason that this volume has been prepared. Although it is now many years since the X rays first entered seriously into practical surgery, yet of recent years the improvement in apparatus and in technique has been so great that the diagnosis and the control of fractures have reached something of finality. The fine focusing tube, the duplitised film, the high-power tubes of the Coolidge type, and stereoscopic photography are examples of this great advance in equipment. The first part of the volume deals with the normal anatomy of the three bones with an extensive series of radiographs illustrating the progress of bone formation through the years of growth. There follows excellent advice on the duties of the radiologist, the general rules governing the radiological examination, and the indications which control the necessity for rontgen photography. A short general review is given of the symptomatology, examination, treatment, complications, and sequelæ of fractures of the upper extremity. This section contains in outline form some of that common-sense information which many students consider so elementary as to be beneath their notice; yet it forms the basis of the successful intercourse between doctor and patient. The fractures of the upper end and shaft of the humerus are well dealt with and the recommendations for treatment show little difference from that commonly accepted in this country. The section on fractures at the elbow-joint is full of interest, and the author's results in this class of case seem unusually good. The method of hyperflexion and complete supination after perfect reduction insisted upon here was taught originally by Sir Robert Jones; but in the original description of Jones's method the hand was suspended by the wrist by a band around the neck, which destroys the complete degree of supination. Eliason has noted this and recommends that the limb should be maintained in plaster-of-Paris in a very useful manner. The chapters on the radius and ulna are well done, but exclude Colles's fracture as this is dealt with in a separate volume in the series by another author. The book ends with chapters on the treatment of compound fractures and of delayed and non-union. There are 303 illustrations. The book is well presented, and forms a valuable addition to the literature of this subject.

---

3. *Traumatic Injuries of the Carpus.* By KELLOGG SPEED, M.D., Assistant Professor of Clinical Surgery, Rush Medical College of the University of Chicago. Pp. 197.

THIS is a companion volume to the one reviewed above, and it contains the fractures at the lower end of the radius as well as those of the carpus itself, Colles's fracture being omitted from the other work—an arrangement which makes the title of this volume inappropriate. The anatomy of the wrist-joint is adequately dealt with, and the radiographic and descriptive presentation of the morbid pathology is good, but the section on treatment is disappointing. As a general rule, the Colles's fracture is badly treated for the reason that the fractured ends are not disimpacted. Until this is done any attempt at reduction must be futile. The description on p. 47 of this book in no way emphasises this important point. The only other reason for bad function after reduction is that the radial deviation of the lower fragment is allowed to persist. This is not recognised by Dr. Speed, and it is definitely laid down that there is no need to put up the hand in the ulnar deviated position. Apart from this, the treatment advocated is the maintenance of the wrist and hand in flexion upon a plaster splint. This method, especially when combined with ulnar deviation, gives results greatly superior to the old methods of Carr's and similar splints.

The second part of the book is much better in every way than the first. The description of the fractured scaphoid and dislocated semilunar are admirable. There are 164 illustrations, many of them simple line drawings. We fail to understand why the price of this book is the same as Prof. Eliason's, which has nearly twice as many pages and illustrations.

# MEDICINE AND THE LAW.

### *Evidence or Opinions Reflecting upon Absent Practitioner: Want of Legal Remedy.*

THE recent suicide of a young barrister at Stoke Newington received additional publicity because his death was believed to have followed psycho-analysis. According to the report in the *Times*, the coroner for Central Middlesex, giving evidence as an old friend of the family of the deceased, stated his belief that there were cases in which psycho-analysis would do good, but that in the majority of cases, and especially in such a case as this, it did harm. The coroner for Hackney, who was holding the inquest, subsequently observed to the witness, "Obviously psycho-analysis can come up against people who are suicidal, and who would in any case commit suicide; having allowed for possible usefulness in some cases, you say that psycho-analysis is sometimes a danger?" Whereto the witness replied: "It can be a very dangerous weapon." These general statements were moderate enough, but the witness also gave his opinion that the cause of the condition of the deceased was the psycho-analytical treatment he had received. From this and other comments the public would not unnaturally infer that the system of treatment is discredited and that the practitioner who administered it made at least a grave error of judgment. It therefore seems unfortunate that this practitioner was not offered an opportunity of giving evidence in defence and explanation of the treatment he administered. One can imagine cases, containing perhaps more serious and specific allegations, where a doctor's reputation might be gravely prejudiced by *ex parte* statements to which he had no chance of reply. It will probably surprise the medical profession to find how little legal remedy the practitioner has in such a contingency. The matter, indeed, is not so much one of law as of practice. As a matter of law a coroner has wide latitude in conducting his inquisition. He can call whatever witnesses he thinks may help the object of his investigation. They may wander unchecked into matters of hearsay or of personal opinion. The coroner is not confined by the rigid rules of evidence and relevancy which fetter other courts, for he is holding an inquiry and not a trial. He is collecting facts which may lead to criminal proceedings, but he is not arraigning an accused person upon a formal indictment. If he exclude hearsay evidence or vague expressions of opinion on the ground that a judge trying a prisoner at assizes would rule such matters out, then he may be rejecting some valuable clue; in the familiar words ascribed to Mr. Justice Wills in the Crewe murder trial some 30 years ago, he may be throwing away much of the remaining usefulness of the coroner's inquest. But, if free from the restrictions of a judge, the coroner has a judge's privileges. He cannot be sued for what he says or does in the exercise of his judicial functions, unless, indeed, he acts in excess of his jurisdiction. No slander action will lie against him for his summing-up. His inquest might be quashed if there were a miscarriage of justice as a result of excluding evidence which might have thrown light on the matter; but interference of this kind is rare and the justification for it seldom arises. Criticism of the conduct or qualifications of a man who may not himself be a party to the proceedings before a court is one of the hardships of all English procedure. In an action between A and B, or in a criminal prosecution of C, the most venomous evidence may be given and the severest forensic and judicial observations may be made against X, and yet X may have no right whatever to intervene in his own defence. It is common knowledge that in many cases of fraud or violence the defendant tries to throw the blame on someone else, often on someone not before the court. Counsel may be present to hold a watching brief for the person thus attacked, but the judge cannot be compelled to hear counsel on his behalf and, indeed, frequently refuses to do so. With his less restricted powers the coroner can be more generous. The judge is bound to confine the proceedings to prescribed issues narrowed down to the smallest compass; the coroner is not. It would therefore be a welcome procedure if it were made an invariable rule at inquests that, where a medical practitioner is directly or indirectly criticised, adequate opportunity should be given him to explain or defend himself. In the High Court of Parliament there is an excellent and honoured tradition that, if a member is to be attacked, he should have notice so that he may be present to reply. A similar tradition might well be encouraged in other courts. The circumstances are different, but the principle of fair play is the same.

### *Action for Fees: Unsuccessful Defence of Professional Negligence.*

Professional negligence is a sufficient defence to a claim by a practitioner for professional fees. But, as Lord Halsbury's "Laws of England" pointed out, the patient cannot evade the payment of fees merely by saying that the treatment was ineffective or mistaken, unless the mistaken treatment is the result of ignorance or negligence. And it is not negligence for a doctor to give an opinion which is afterwards found to be wrong, provided that the opinion was not given negligently. This principle of law is illustrated by a recent case in the Harrogate county court, in which Dr. James N. Todd sued Mr. R. S. Wigan, a retired solicitor, for 14 guineas for professional services rendered. The defence was an allegation of incompetence and erroneous diagnosis. The county court judge awarded Dr. Todd the full amount of his claim and special costs. From the report of the case in the *Yorkshire Observer* it appears that the defendant did not dispute the amount of the fees, but contended that the plaintiff had displayed a want of competent and ordinary care and skill in successively diagnosing several diseases. It was stated that Dr. Todd had been called in to the defendant in March, 1921, when he diagnosed blood pressure; on the following day, it was said, he diagnosed jaundice; afterwards he said he feared cancer, and at a later date he suggested diabetes. These statements, on behalf of the defence, were combated by the plaintiff. Mr. Herbert Frankling, a surgeon of Harrogate, and Mr. L. R. Braithwaite, a surgeon of Leeds, gave evidence on behalf of Dr. Todd, and there were other medical witnesses. In giving judgment his honour Judge A. W. McCarthy said he could not find a single trace of negligence on the part of Dr. Todd. All that was required of a professional man such as the plaintiff was that he should bring to his work reasonable skill and competence. The law did not require that a professional man should always be right. That would be impossible. In his diagnosis Dr. Todd was apparently correct. He was satisfied that there was cancer but he apparently expressed his opinion in rather too dramatic a manner. There was, however, nothing unprofessional in that. The learned judge concluded by stating categorically that there was not the slightest justification for saying that Dr Todd had shown any want of ordinary skill or competence in treating the defendant, and there was no foundation whatever for the allegations made against him.

### *Silicosis and the Coal-Miner.*

The case of Williams *v.* Guest Keen and Nettlefold, Ltd., recently decided in the Court of Appeal, reveals a curious gap in our system of workmen's compensation. Absalom Williams, a coal-miner, had for years been operating a coal-boring machine worked by compressed air. In June, 1922, his lungs became affected and he had to give up his work. In 1923 he resumed it; subsequently he broke it off again and again returned to it, and in April, 1925, he was totally incapacitated, the inhalation of dust particles over a period of years having brought on silicosis. Now a slow and cumulative disease of this kind is not regarded by the law as "personal injury by accident" within the meaning of the Workmen's Compensation Acts. Some industrial diseases of a gradual nature (lead poisoning, for instance) have, it is true, been scheduled as legally equivalent to "personal injury by accident" in certain specified trades; but silicosis is not one of them. All that Parliament has said about silicosis is that provision may be made by the Home Office scheme for compensating workers suffering therefrom in particular industries. Such a scheme was duly made for what are called the refractories industries (i.e., mines, quarries, factories, or workshops where refractory material containing not less than 80 per cent. of silica is got or manipulated), but it does not extend to coal-mining. The result is that, though there are three different ways in which a workman can obtain compensation—for a personal injury due to accident, or for a scheduled industrial disease, or under the Home Office silicosis scheme—the coal-miner who contracts silicosis in the course of his employment cannot avail himself of any of them.

The decision of the Court of Appeal merely confirms what was already known to be the law. In 1905 (Steel *v.* Cammell Laird and Co.) a ship-caulker whose task it was to smear red and white lead upon rope yarn and to work it in with his hands, gradually accumulated lead in his system until he became partially paralysed and incapable of work. This occurred before lead poisoning had been scheduled as an industrial disease, and the law courts held that a disability which came so gradually upon its victim could not be personal injury by accident. Though there was a day when he was suddenly seized with cramp in the hands, it was not thought possible to indicate a moment at which there was an accident which caused his injury. The law thus laid down was held to preclude Williams from recovering compensation in the recent case mentioned above. That a disease may be the result of an injury caused by an accident was admitted many years ago in Brintons, Ltd. *v.* Turvey, where a woolsorter was infected with anthrax and died within a week. Lord Halsbury then said that if a tack or some poisoned substance cut a workman's skin and set up tetanus, it would obviously be an accident even though tetanus is a disease. Similarly, if some corrosive acid were spilt over the workman's hands and set up erysipelas, it would be an accident. And so the House of Lords held (Lord Robertson dissenting) that the anthrax was caused by an accident or, as Lord Macnaghten said, a chapter of accidents. More recently in 1921, in Charles Burrell and Sons *v.* Selvage, where a workman had suffered for months from cuts and scratches and the cuts became septic, the consequent total incapacity was held to be an accident within the meaning of the Acts, though no one of the series of minor accidents could be identified as the cause of the incapacity. But the silicosis of Williams was due to no such causative accident in the eyes of the law, and this unfortunate coal-miner has had no legal remedy.

### *The Coroners' Bill and Deaths under Anæsthetics.*

At an inquest lately held upon the body of a man who died under an anæsthetic in hospital, the coroner for the City of London commented upon the omission from the Coroners' Bill of any specific provision for inquiry into such cases. Dr. F. J. Waldo stated that he had reason to believe that many such deaths occurred in private houses and nursing homes and were not reported to the coroner. The Coroners' Society, he added, had long ago come to the conclusion that no death resulting from the use of an anæsthetic, for whatever purpose administered, should be certified as a natural death, but that it should be the duty of every householder or occupier upon whose premises such a death occurred to give immediate information to the coroner or his officer. One of the first clauses in the draft consolidating and amending Bill printed and published by the Coroners' Society in 1913 was a provision for compulsory notification to the coroner of all such deaths; such a reform, said Dr. Waldo, would lead to an improvement in the collection of statistics which at present are often useless and misleading.

The Coroners' Society's draft Bill of 1913 undoubtedly contained much that was useful and well considered. If it was not wholly acceptable in official quarters, the reason may be that the clauses relating to coroners' status and emoluments were thought to be too optimistically conceived. In any case the Government Bill, withdrawn at the end of last session but likely to be passed into law this year, at present holds the field. It is true that it does not contain the particular reform which Dr. Waldo advocates, but there is so much of value in the Bill that it seems almost ungrateful to ask for more. The proposed abolition of franchise coroners, the substitution of a uniform system of annual remuneration for payment by inquest, the power to adjourn inquests pending the conclusion of a murder charge and to discontinue the inquiry if the result of the criminal proceedings justifies that course—these are reasonable reforms which were overdue. Other fresh features of importance recommend themselves—the newly-framed power to summon medical experts (though it is not quite clear what will happen if several coroners desire the attendance of our chief experts on the same day), the machinery for holding a single inquest where several deaths, due to one and the same accident, occur in the jurisdiction of different coroners, the power to hold an inquest though the body is destroyed or irrecoverable, the cautious provision for taking a majority verdict from the jury, and the removal of the absolute obligation that the jury should view the body, a duty which is seldom necessary save where there are wounds which raise the question whether the injury is self-inflicted or not. While we should be sorry to see the success of so useful a Bill jeopardised by too much criticism, Dr. Waldo is right, of course, to insist upon the importance of obtaining all possible information as to the effect of the different anæsthetics. Useful statistical results might follow the properly coördinated administration of that clause in the Bill which empowers post-mortem examination where there is sudden death from a cause unknown and where the coroner thinks a port-mortem might prove an inquest unnecessary. But this clause does not meet the case of deaths under anæsthetics. A proposal which might have the effect which Dr. Waldo desires has been discussed from time to time, but is understood to lack the support of the Coroners' Society. It is that the coroners should nominate a panel of acknowledged experts in physiology whose services would be available for investigating all cases of deaths under anæsthetics in hospitals, provision being made that no expert should be asked to investigate a death at his own hospital. Such a plan would provide the statistical data which we require. Certainly it would in most cases render an inquest unnecessary.

---

HOME FOR PATIENTS WITH FUNCTIONAL NERVOUS DISORDERS.—Caldecote Hall, near Nuneaton, was recently opened as a home for certain types of functional nervous disorders under the auspices of the Church of England Temperance Society. Caldecote Hall, a fine modern Jacobean house, succeeds an older building which was besieged and taken, under romantic circumstances, by Prince Rupert in 1642. The cases taken include drug addicts and inebriates and those with suicidal tendencies and so forth. Fifty beds are at present available and it is proposed later to increase the accommodation to 100. The terms vary, according to bedroom accommodation, from 3 to 12 guineas weekly. A "poor patients" fund exists in order to help those who have small means to enjoy the benefits of the home, which is run on the lines of a country club by a committee of the patients themselves. A canteen is provided, working on a token system, the profits from which are devoted to the sports fund. Tennis, croquet, and bowls are available out of doors and billiards indoors. Sir William Willcox and Sir James Purves-Stewart are consulting physicians. Further particulars can be obtained from the R.M.O., Dr. Alfred Carver, at Caldecote Hall, near Nuneaton, or from the Secretary, at 40, Marsham-street, London, S.W. 1.

# THE LANCET.

*LONDON: SATURDAY, JANUARY 9, 1926.*

## THE EFFECTS OF CORONARY OCCLUSION.

IN these days, when the chief advances in medicine come from the laboratory or from the application of experimental methods, it is of some interest to record a noteworthy advance in clinical descriptive medicine. We are so prone to regard the fields of clinical observation and of pathological anatomy as fully charted, that it comes almost as a surprise to find that we have had before us a more or less clear-cut syndrome due to a definite acute pathological accident, which is not generally recognised clinically and which is actually not accurately described in the majority of current text-books. That angina pectoris can be associated with disease of the coronary arteries has been known since the observations of EDWARD JENNER, who found this condition at the autopsy of his friend, JOHN HUNTER. That sudden obstruction of the coronary arteries, or of one of their principal branches, is a frequent cause of sudden death is a commonplace of the coroners' courts. It is also well known that obstruction, either sudden or gradual, of a branch of the coronary artery can produce pathological changes in the cardiac wall varying from ischæmic necrosis to fibroid substitution according to the stage. It is less common knowledge that such obstruction can produce a series of symptoms which enable it to be recognised with some degree of certainty.

In the October number of the *Quarterly Journal of Medicine* there is a paper by Dr. J. W. MCNEE giving a clear account of the clinical syndrome of coronary thrombosis, based on three cases seen at the Johns Hopkins Hospital, Baltimore. This paper deserves careful study. Dr. MCNEE points out that the condition has received special recognition in the United States of America, and refers to a considerable literature concerning it. He maintains that the main clinical features are agonising pain lasting longer than the pain of similar character occurring in angina pectoris. It is probable that the condition hitherto described as "status anginosus" is of this character and owns this causation. The distribution of the pain is often anomalous, and may give rise to the suspicion of perforated gastric or duodenal ulcer, cholelithiasis, or acute pancreatitis. A peculiar colour and appearance of the face is described—*namely*, an earthy colour with definite though slight cyanosis. As might be anticipated, coronary thrombosis is immediately followed by signs of acute heart failure, with the indications of cardiac embarrassment and the signs of pulmonary, hepatic and renal engorgement. A localised pericardial friction in association with these clinical manifestations is pathognomonic, but is not constant and may be extremely evanescent. Fever and some degree of leucocytosis are always present, and some abnormalities in the electrocardiographic records are common, but not characteristic.

Two important papers have appeared in recent issues of THE LANCET dealing with the same subject, supplementing in a useful and noteworthy fashion the observations recorded by Dr. MCNEE. It is of some interest to note in this connexion that one of the earliest if not the first observations on this subject, from the pathological point of view, was published in our columns as long ago as 1887 by Dr. J. L. STEVEN, of Glasgow. In the first of the two recent papers Dr. A. G. GIBSON, of Oxford, critically examines the symptoms recorded in some 43 cases, including some observed by himself; he also includes brief descriptions of cases under the care of Dr. JOHN COWAN, Prof. F. R. FRASER, and Dr. K. D. WILKINSON. Dr. GIBSON's observations in the main confirm those of Dr. MCNEE and the American observers, but he also includes the more severe cases in which sudden death or rapid cardiac failure occurs. In addition to the localised pericarditis, which so frequently occurs, he points out that clot often forms on the endocardial side of the ischæmic or necrotic area, leading not infrequently to embolic phenomena. He goes so far as to state that in old people chronic cardiac failure complicated by aseptic embolism makes the diagnosis of *ischæmic necrosis practically certain*. Another result to which he refers is weakening of the heart wall to such an extent that rupture occurs. Dr. GIBSON refers to the pulse in ischæmic necrosis. He mentions that Sir JAMES MACKENZIE noticed pulsus alternans in two of his cases. Auricular fibrillation has also been observed. He suggests that a recent paper by COWAN and BRAMWELL[1] seems to indicate that bundle branch block may frequently be present in these lesions. The other paper, published in our issue of Jan. 2nd by Dr. CAREY F. COOMBS and Dr. GEOFFREY HADFIELD, is noteworthy, not only for the admirable coloured plate with which it is illustrated, but also for the useful classification of the clinical types observed as a result of coronary occlusion. They group these under three heads, viz.: First, cases with acute ventricular failure, corresponding closely to the syndrome described by Dr. MCNEE and the American physicians; second, those with chronic cardiac failure; and third, cases with unrecognised symptoms dying before diagnosis is established. Dr. GIBSON, in his useful comments on the cases studied by him, suggests that there still remains an enormous field for study in these cases, particularly in regard to the correlation of symptoms with special anatomical lesions. He states that attempts to deduce the site of the lesion from the symptoms have proved unreliable, and further, that there appears to be no relation between the size of the lesion and the severity of the symptoms, a somewhat surprising statement.

It is to be hoped that the clear accounts given by these various observers will serve to direct more general attention to this interesting and important condition. Dr. G. KLIONSKY's note on p. 74 is an earnest of what may be expected.

◆

## THE BRITISH PHARMACOPŒIA.

A PROFESSOR and learned physician who was placed on a committee to make suggestions for the revision of the British Pharmacopœia, gave good help in this task, for he had a great experience in the action of drugs, but he confessed that he had never seen a copy of the work. That is a story which bears exact relation to one of the difficulties which the General Medical Council at the present time is experiencing. The Pharmacopœia has the first sort of official backing, but it is not generally consulted by the practitioner, and many medicines that are in common use obtain no mention in its pages. Why had the professor not seen the book? The Medical Act of 1858 enacts that the General Medical Council shall cause to be published a book containing "a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures, by which they are to be prepared and mixed." The term "a list of medicines" is vague enough, and leaves much to the discretion of the Council. It is generally accepted that only well-tried drugs and those whose exact composition can be defined shall be made official, and as each new Pharmacopœia comes round there is much talk as to which of the recent inventions shall be admitted, and which of the redundant ones shall be dropped. Additions and excisions have been carefully and skilfully accomplished, while, as far as the former are concerned, there are always many drugs of common use which, perhaps because they are not sufficiently tried, perhaps because more efficient ones have been invented, perhaps because their method of preparation is not exact enough, can find no place in the official list. Any list, however carefully compiled, would be open to criticism, and the British Pharmacopœia may be too exclusive, but this is a fault in the right direction.

---

[1] Quarterly Journal of Medicine, October, 1925, p. 95.

Now, if to give, over a sufficiently wide range of material, the names of drugs and their doses were the sole object of the Pharmacopœia, it is probable that the official volume would be well known to doctors. The words, "manner of preparing" drugs and their compounds, however, introduce a different issue. The practitioner of 100 years ago prepared many of his own drugs himself, but his successor of to-day would be at a loss to prepare the simplest of his remedies, and instruction upon the matter is largely wasted upon him. His acquirement of pathological knowledge and of the experience which will give him skill in diagnosis, leaves no space in his curriculum to work at an art which can well be carried out by those whose curriculum is more specialised and not so long; in a shorter time they can make themselves more perfect than he can hope to do. It is ordained, and rightly we think, that this information as to how to prepare medicines and compounds should be published in the Pharmacopœia, for a public standard has to be maintained; but its inclusion makes the volume, though ultimately for the practitioner's use, something of an embarrassment to him. And when the information in the Pharmacopœia goes to fine extremes in securing the exact preparation and complete purity of the drugs with which it deals, much labour and wisdom are wasted if, by chance, certain of these drugs are not in common requirement. Because, therefore, the Pharmacopœia includes unnecessary matter as far as modern therapeutics are concerned, and because it is slow to adopt new remedies other works are found more acceptable by the profession, but even so the practitioner does use the British Pharmacopœia, even though individually he has never seen it, for these other works, whether by physician or pharmacist, are all based on it. The books omit much of the information as to the preparation of drugs with which it is lumbered, and add to it in other ways, one by showing the application of drugs, others by describing medicines which have not yet obtained their foothold in the national book or which are still only in their "proprietary" stage. It has been argued against the General Medical Council that its book is heavy and lifeless. We hope we have shown that this heaviness —in so far as it betokens accuracy—is a virtue rather than a vice.

Other troubles have arisen in the preparation of the new Pharmacopœia. It has been customary for the General Medical Council, at the time of the preparation of each edition, to invite the help of others to join in the preparation. Naturally, the most important invitation goes to the Council of the Pharmaceutical Society. Formerly the aid thus asked has been given. Now the Pharmaceutical Society, which certainly is able to supply a larger share of the knowledge required to make a Pharmacopœia than any medical body can do, objects to a mere invitation and claims its right to representation. The suggestion made by the General Medical Council to the Pharmaceutical Society was to set up, in the first place, a Pharmaceutical Advisory Committee, consisting of three members from each body with the President of the General Medical Council as chairman; and, in the second place, a Committee of Reference in Pharmacy, to be nominated wholly by the Pharmaceutical Society, to consist of expert pharmacists and to deal with questions bearing on pharmacopœial pharmacy. Both these committees were to be advisory, the General Medical Council reserving its freedom to adopt or disregard the advice and suggestions offered. The Pharmaceutical Society rejected this proposal, insisting on actual representation on the Pharmacopœia Committee as essential. In a letter to the Privy Council the Society expresses dissatisfaction at the present conditions of production, finding the intervals between successive editions of the Pharmacopœia too long, each edition being in some respects out of date when published, and the work of preparation inadequate. The Society reminds the Privy Council that one of the two editors of the 1914 edition was Prof. H. G. Greenish, dean of the Society's School, and the Privy Council is asked to give the Society, as in the case of the national pharmacopœias of other countries, some effective voice in deciding upon the methods and extent of pharmaceutical research to be undertaken in preparing the Pharmacopœia, and upon the extent to which the purely pharmaceutical matters in the Pharmacopœia require modification. It is the view of the Pharmaceutical Society that no legal obstacle exists to prevent the granting of such representation, and the Society requests the Privy Council to inquire what alteration of the law, if any, is needed in order to secure the preparation of future editions of the Pharmacopœia upon a satisfactory basis. The claim of the Pharmaceutical Society seems to us fair enough on general principles, for, as we have stated, bulk for bulk, a bigger share of the Pharmacopœia is pharmaceutical than medical. It must, however, be remembered that the General Medical Council works under the Act of 1858, and it appears to us that, if a change is to be made, it will depend on a change of constitution of the Council rather than on any internal action of the Council itself. It would seem wiser, if a change is to be made, to take steps as soon as a new pharmacopœia has been issued, rather than while one is in active preparation. The "Locarno" spirit will, at the present time, suit best these two branches of the art of healing which have of recent years been working so well together.

◆

## LABOUR PAINS.

Physiologists have much reason to be proud of their work during the last half century. Questions which never occurred to their forefathers have been faced and answered. On the other hand, some of the most familiar phenomena in human physiology are as perplexing now as they were at the dawn of medical science. One of the most striking of these is the process of labour. A child is born every minute, but no one has yet explained why the fœtus is expelled automatically at full term or the exact part played by the unstriped muscle of the uterus in the process. The pains of labour are proverbial, but no one has yet given a reason why this normal physiological process should be such a painful experience, why some pains are strong and others weak, and why the process of expulsion in a normal pelvis sometimes encounters overwhelming resistance and sometimes none at all. "Lieferung XX." of the new German text-book on gynæcology[1] contains 200 pages on the expulsive forces alone, contributed by Prof. HANS GUGGISBERG, of Berne, who expatiates on the experimental investigation of uterine activity, the results of artificial stimulation, the clinical aspect of pains, the various theories of the exciting agency of labour, weak and strong pains and their therapeutic control, and his treatise may be confidently referred to as an exhaustive and up-to-date study of the subject. But the student who hopes to extend his knowledge of the essential physiology of birth will find in it little to satisfy him, for whenever the scent freshens he comes up against a baffling wall in the author's conclusion that "in the present state of our knowledge we are unable to answer this question."

In discussing the reason for the painfulness of labour, Prof. GUGGISBERG compares the process to peristalsis, which becomes painful if it is resisted, and points out that the uterine muscle meets with more resistance in the performance of its function than any other muscle of the body. The pain varies largely with the state of the soft parts, and elderly primiparæ are on this account liable to severe labour, while patients with placenta prævia, whose soft parts are slack, may undergo several hours of labour before they feel pain. Other causes of pain are the pressure to which the pelvic organs are subjected and the stretching of the peritoneum incident to the uterine contractions. He contrasts human labour with that of animals, noting that in the former the cervix and vagina are passive, while in the latter the vagina plays an expulsive rôle. The chief function of the human vagina seems to be to expel the placenta. Animal experiments have thrown little light on the part played by the various nervous connexions; the uterus appears to have its own controlling ganglia and will function perfectly well even if its connexions with the cerebral, spinal, and sympathetic systems have been severed. The experiments give widely differing results not only in different animals of a species, but also in the same animal at different stages in the reproductive process. There seems no doubt that the contractions can be affected through the motor centres of the central nervous system, and anæmia of the brain can act as a stimulant, but this aspect has been very little investigated and has at present no therapeutic significance. Reflex stimulation—that, for instance, of a loaded alimentary tract or bladder—is well known to inhibit "pains," which can be also excited from the skin. GOTTLIEB showed that irritation of the intestine led to heightened blood pressure in the pelvis and reflex excitation of the uterus.

It is this autonomy of the uterus that has limited obstetric drugs to those which act directly on the uterine musculature, such as pituitary extract and quinine, but stimulation via the sympathetic and autonomic nerves may be of value under certain circumstances. SCHIFFER and KURDINOWSKI have demonstrated the rapid and efficacious action of adrenalin on the contractions, and the former has recommended its use therapeutically in conditions of hæmorrhage. Prof. GUGGISBERG thinks that it is indicated in atony with post-partum hæmorrhage and in Cæsarean section, in doses of 0·1 to 0·3 mg. directly injected into the body of the uterus. NEU observed a tonic contraction of the os after its administration, and for this reason and on account of the idiosyncrasy of some women to the drug it must be used with considerable caution. Prof. GUGGISBERG lays stress on the value of reassurance in primary inertia and urges the practitioner to be content to do nothing save comfort his patient. Vaginal examinations he strongly deprecates. His views on the use of pituitary extract, ergot, and quinine correspond with those commonly held in this country. Quinine is mild and hardly ever causes cramp or other bad results, but its uncertainty restricts its use to the second stage, when pains are weak, and to abortions. Ergot he thinks chiefly valuable during the period immediately following expulsion, especially when the muscular tone is bad, and prefers it to pituitary extract because it is milder. Combined with this extract it reduces bleeding in Cæsarean section to a minimum. Pituitary extract has the advantage of being a natural substance produced by the body itself and not a foreign introduction, and on the whole he does not regard it as dangerous

All this, however, has been said before, and the fact that a text-book of this magnitude has to confess ignorance on almost every page should act as a strong spur to investigators. Obstetricians are tending more and more nowadays to "leave everything to Nature," and if this clinical attitude is to be justified it would be as well to know a little more clearly the processes by which Nature works.

# Annotations.

"Ne quid nimis."

## THE NEW YEAR HONOURS.

THE list of New Year Honours, though short, contains a number of names representing various branches of the medical profession. Sir Robert Jones, who has become a baronet, is identified with recent progress in orthopædic surgery. Surgeon Vice-Admiral Joseph Chambers, who has been promoted to K.C.B., is the head of the Medical Department of the Navy. Dr. Robert Bolam, one of the new knights, is Chairman of Council of the British Medical Association. Lieut.-Colonel Frank Powell Connor, D.S.O., I.M.S., professor of surgery and surgeon to the Bengal College of Medicine, Calcutta, and Dr. Henry Alfred Alford Nicholls, lately P.M.O. to Dominica, Leeward Islands, have also received the honour of knighthood, while the C.I.E. has been conferred upon Lieut.-Colonel John Wallace Dick Megaw, I.M.S., Director of the School of Tropical Medicine and Hygiene, Calcutta, and upon Major Robert Henry Bott, I.M.S. Dr. Frederic Joune Willans, Surgeon Apothecary to H.M. Household at Sandringham and to the late Queen Alexandra, has been promoted to C.V.O. Dr. Jessie Carleton, of the American Presbyterian Mission, Ambala; Dr. Jessie Matilda Allyn, of the Canadian Baptist Telugu Mission, Pithapuram, Madras; and Dr. Charlotte Leighton Houlton, medical officer in charge of the Lady Reading Hospital for Women and Children at Simla, have received the Kaisar-i-Hind medal of the first class for public services in India. To all these recipients of well-merited honours we tender hearty congratulation in the name of the medical profession.

## REFORM OF THE POOR-LAW.

SINCE an Act of Queen Elizabeth directed that three or four substantial householders should act as overseers of the poor in every parish, the ultimate responsibility for the relief of the destitute has gradually passed, by way of Poor-law Commissioners and the Local Government Board, to rest at last in the Ministry of Health. Yet the local guardians elected to deal with their own parishes have survived the changes of 325 years. They have carried out their duties with more or less success, and it is only the growth of other machinery of local government, whose sphere of influence and work often overlaps that of the guardians, which has convinced most political leaders that the guardians themselves are obsolete. It is to be hoped that a measure of Poor-law reform will never be the subject of party bickering, and it is well that the Minister of Health should allow plenty of time for consideration of his new proposals by those concerned before pressing a Bill upon Parliament. These proposals will probably meet with the approval of theorists (who are often right), but they have already raised something of a storm in the parishes. The Minister's circular sums up his proposals in the following words:—

---

[1] Biologie und Pathologie des Weibes. Ein Handbuch der Frauenheilkunde und Geburtshilfe. Josef Halban and Ludwig Seitz. Urban and Schwarzenberg. Berlin and Vienna. 1925 Pp. 1059. Die Wehen.

1. The coördination and improvement of the provision made for the prevention and treatment of ill-health, both institutionally and otherwise, and the inclusion in this provision of all public assistance required as the result of sickness, accident, and infirmity.

2. The coördination of all forms of public assistance, and especially an improved correlation between Poor-law relief and unemployment benefit.

3. The decentralisation of the responsibility at present falling on the Minister.

4. The simplification of the financial relations between the Ministry and the local authorities and the freeing of the local authorities from the financial restrictions in matters of comparative detail which are a necessary concomitant of the present system.

5. The correction of certain anomalies of historic origin, such as the association of the registration service (births, deaths, and marriages), with the provision for the relief of the poor.

The two main suggestions are that boards of guardians should be entirely abolished and that their functions should be transferred to the county councils and county borough councils. The county councils are to be the administrative units and are to be freed from central government control, as far as their health services are concerned, by receiving block grants of money which will supply their needs over a period of years and will enable them to deal with their own problems without frequent application to the Ministry for sanction of details. County councils will be entitled to delegate their new duties to borough and district councils, who will be expected to bear the cost of their own work but may receive additional grants from the counties. The assigned revenue system will be abolished, but local taxation licence duties at present levied by county councils and county borough councils will still be levied by them.

Critics of the proposals feel strongly that the county councils, whilst giving uniformity to the administration of relief in their areas, will lack the local and personal knowledge which boards of guardians have possessed. The councils, it is suggested, have already a vast amount of work to do, and the Minister's proposal that their membership should be enlarged to include ex-guardians who have special knowledge does not altogether meet the objection that the service of poor relief will lose a good deal of that voluntary work which is so valuable. It is feared that it will tend, unless checked, to fall largely into the hands of paid officials. The paid official is a necessary part of any scheme, but English tradition always—and rightly—prefers him as the servant of an elected and executive body which takes a continuous and unremitting interest in his work. It is the failure of a few elected bodies to do their work properly and with responsibility that has finally forced reform upon us after many years of vague discussion. The extension of the municipal franchise has placed power in the hands of the wage-earner rather than in those of the ratepayer, and it is intolerable, as the Minister implies, that the election of guardians should depend on how much they will offer to pay to the unemployed. The Minister evidently believes that by making poor relief a part of the functions of a larger body—the county council—he can abolish this abuse. His critics fear that the abuse will be transferred to the councils themselves, and that popular clamour for relief will rule these elections also.

Mr. Neville Chamberlain's plans for the future of the hospitals can conveniently be discussed at another time, but it may be mentioned that his memorandum suggests that the reforms ought to make the amenities of Poor-law medical institutions available and acceptable to all classes of the population. In many of them the facilities for treatment are excellent, and it is very desirable that they should no longer remain out of the reach of many sections of the community who either cannot or will not bring themselves within the scope of the Poor-law.

## PUBLIC TREATMENT OF TUBERCULOSIS.

With the New Year there came into operation an instruction of the Ministry of Health (Mem. 37/T) to all local authorities responsible for the treatment of cases of tuberculosis, by which it prescribes uniformity of records and statistical returns. As the Ministry pays half the expenditure of local authorities in treating cases of tuberculosis, it has some right to call the tune and to see that the public gets full value for the money it spends. The Ministry desires to know what progress tuberculosis schemes are making, what is the volume and character of the work being done, and what are the immediate and ultimate results of treatment under each scheme. With this end in view it requires the keeping of uniform records and the presentation annually of certain uniform statistical information. Such administrative control is no doubt inevitable, but the duty of furnishing the information which the Ministry requires, although the latter is stated to be reduced to a minimum, undoubtedly entails a considerable amount of extra clerical work for those in charge of tuberculosis dispensaries. The demand for uniformity in work may be expected to produce here, as it does in similar cases, some raising of the standard of work in the less efficient dispensaries and institutions, but it may at the same time hamper and discourage those who set up high standards of performance.

The memorandum has been incubating at the Ministry for several years and has been the subject of consultation between the Ministry's officers and tuberculosis workers of all branches. Though regarded by the latter as a disagreeable necessity, it has been moulded to reconcile as far as possible many divergent points of view. The basis of the uniformity aimed at is the new system of classifying patients suffering from tuberculosis which the Ministry imposes. This system, though stated to be purely tentative, pending agreement among clinicians on a better system, cuts right across all existing systems of classification, and renders statistical comparisons with previous years and other countries almost impossible. It is, therefore, all the more to be regretted that a new system should be put forward which itself shows defects so far as it applies to cases of pulmonary tuberculosis. In several respects it marks a considerable advance, notably in putting in two different classes cases in whose sputum tubercle bacilli have at some time or other been demonstrated and those in whose sputum they have never been found. Thus are separated the cases where there can be no doubt of the accuracy of the diagnosis from those in which there must always remain some doubt. The Ministry has done well also in laying emphasis on the degree of constitutional disturbance present, since this has more value in assessing a patient's prospect of recovery than the mere extent of lung involved. The "T.B. plus" cases are sorted into three groups, the first of which must have physical signs and symptoms of such limited degree that probably no more than 10 or 15 per cent. of the cases ordinarily treated in a sanatorium would satisfy the criteria. At the other end of the scale is Group 3, equally limited in numbers and defined as follows:—

> "Cases with profound systemic disturbance or constitutional deterioration; with marked impairment of function, either local or general, and with little or no prospect of recovery. All cases with grave complications, whether tuberculous or not, should be classified in this group—e.g., diabetes, tuberculosis of larynx or intestine, &c."

These criteria seem to be not alternative but cumulative, and it is unlikely that a definition, to which in practice widely varying interpretations will be given, and which is so illogical as to make the classification depend on the prognosis instead of the opposite way about, can stand the test of time. The great mass of intermediate cases, probably 70 per cent. of the whole clientele of the average dispensary, is left to form Group 2 without any means of further subdivision. More successful are the definitions stating the results of treatment—namely, "cured," "arrested," "quiescent," "improved," and "no material improvement" The model case records set out for completion by tuberculosis officers, sanatorium physicians, and panel doctors treating insured cases of tuberculosis appear to meet all requirements. A new feature, copied from the Ministry of Pensions, is that the accumulating records shall form a transferable dossier to be put at the disposal of the sanatorium or hospital when the patient is admitted there, or transferred to another dispensary when the patient moves from one area to another.

The Ministry makes it clear that the general practitioner is expected to provide the ordinary treatment of tuberculous patients where these are insured or can afford to pay for medical attendance. The functions of the tuberculosis dispensary are limited to diagnosis, consultation, and general supervision, with treatment for such patients as require special knowledge or technical skill or cannot obtain other adequate medical attendance. Every patient is regarded as being continuously under the "general supervision" of the tuberculosis officer, and should be examined by him at least once a year. The procedure in regard to contact cases is laid down, and pressure is brought on the tuberculosis officer to make a definite diagnosis in observation cases within two months after the first examination. While some such provision may appear necessary where the tuberculosis officer is easy-going or reluctant to make up his mind, it is conceivable that the rigid observance of this rule may lead in certain cases to ill-considered diagnoses. No 63944

## THE HEALTH OF MERCHANT SEAMEN.

NORWAY, with her long coastline, is one of the foremost seafaring nations, so it is not surprising to learn that the Norwegian Red Cross has taken up the question of the health of merchant seamen. The Red Cross, with its peacetime health programme, is an international body peculiarly well fitted to undertake this task, and it may be recalled that the Norwegian Red Cross, at the Third General Council of the League of Red Cross Societies held in Paris in 1924, appealed to other national societies in this matter The assembled delegates of the 54 National Red Cross Societies thereupon passed the following resolution :—

> The General Council, having taken note of the interesting pioneer work undertaken, in coöperation with Governmental departments, by the Norwegian Red Cross for the improvement of health in the Merchant Service, and believing that this constitutes a new and promising field of Red Cross activity, recommends the National Red Cross Societies of all maritime countries to take part in this activity as far as possible, through the following channels : (*a*) Educational propaganda on board ships, by posters, pamphlets, and other means. (*b*) Improvement of existing manuals on hygiene for seamen, or publication of new ones. (*c*) Establishment of Red Cross health centres with clinics for the medical treatment of seamen. (*d*) Drawing up of plans for the supply of up-to-date medicine chests (*e*) Request to the Norwegian Red Cross, through the intermediary of the Secretariat of the League, to collect the results of efforts undertaken in accordance with (*b*) and (*d*), and to draw up a plan for an international type of medicine chest and manual, based on these results.
>
> The General Council desires to express its conviction that the International Conventions at present under discussion for the prevention of venereal diseases should be extended to include a wider health programme for seamen of the Merchant Service and requests the Norwegian Red Cross jointly with the Secretariat of the League to forward a communication to this effect to the Joint Maritime Commission of the International Labour Office.

In an article published in the January number of the *World's Health*, Dr. Harold Engelson, of Norway, describes the steps which have been taken by the Norwegian Red Cross since the passing of this resolution, and appeals to other nations to assist in the effort to improve the health of merchant seamen. In Norway 21 medical stations have been established by the Red Cross in the principal seaport towns, and doctors have been appointed, whose duty it is to look after all sailors, of whatever nationality, who apply for treatment. Usually these doctors are also medical officers of health, and they carry on this work by special arrangement, in addition to their other duties. A moderate charge is made which the sailor himself is asked to pay, as it has been found that he is willing and able to pay, but often does not know where to apply for help. Dr. Engelsen suggests that it should be stated in the sailor's certificate when he was last vaccinated against small-pox and inoculated against typhoid, paratyphoid A and B, cholera, and plague. He also suggests that the Red Cross doctor should record in a note-book the patient's name, nationality, disease, treatment and date of treatment, and that this book should be handed to the sailor, with instructions to present it next time he requires treatment in a foreign port. The Red Cross on the cover would act as a passport to any Red Cross medical station, and the fact that he had a written record might encourage the sailor to apply for treatment in a foreign port, as it would lessen the difficulty of explaining his case.

The Norwegian Red Cross, while fully recognising the importance of the step which has been taken by the adoption of an international agreement for the establishment of venereal disease clinics for seamen, is of the opinion that the question of the health of merchant seamen should be dealt with in its entirety, not limited to any one disease. Special clinics for the treatment of venereal disease only, it is felt, may deter sailors from applying for treatment owing to a feeling of shame, whereas if medical stations were established in ports throughout the world where all diseases were treated, these clinics would soon become known and valued by seafaring folk. Soldiers and sailors have always had a first call upon the services of the Red Cross and it is not likely that this appeal will be made in vain. Already other national societies are showing their interest. The Greek Red Cross has appointed a committee to consider the question, and this committee has recommended the establishment of medical stations in the principal ports of Greece. The Central Committee of the Norwegian Red Cross Society is considering the possibility of organising this summer a tour of inspection of certain ports in Norway in order that representatives of National Red Cross Societies interested in this matter may study on the spot the working of the Red Cross stations for seamen.

## A GREAT WAR HOSPITAL.

IT has been decided that Bellahouston Red Cross Hospital shall be demolished save a small portion temporarily retained for the Pensions Ministry. During three years of war and in the year following there were received into the hospital 14,807 sick and wounded soldiers drawn from every section of the Imperial forces. The success of the undertaking offers lessons in construction, organisation, and finance. In 1915 a large hospital had to be put up at a time when labour and materials were scarce. It had to be quickly finished and easily expansible. Asbestos sheeting was selected as material and the one-storey bungalow system, with its saving of lifts and stairs, was adopted. The whole was built upon the central corridor plan, the corridor running north and south with blocks opening off it on each side. Between the blocks, each of which held 50 beds and was complete in itself, there was enough space to allow patients to be wheeled out into the air and sunshine. The hospital came into use with 500 beds, but later its size was increased to hold 1200. A special department for orthopædics, curative baths, physical therapy, and orthopædic workshops was added, as well as the necessary annexes for the staff; and the fact that all this was done at an outlay of

£100,000, including equipment, showed that the Scottish Red Cross had been wise in adopting a simpler method of hospital construction than that usually in vogue. The hospital was regarded officially as one of the best arranged and equipped hospitals in the kingdom. In an article contributed to the *Glasgow Herald* Sir George Beatson draws the attention of those interested in the problems of civil hospitals to the experience gained at Bellahouston. The civilian voluntary hospitals, he says, have defects in their construction, their organisation, and their finance, though their management is excellent. The usual type of hospital building is costly to erect, expensive to run, and gives meagre accommodation for the money spent on it. There is also an absence of coördination between the different hospitals. What is needed, he says, is the regional distribution, around central hospitals, of auxiliary hospital groups, and clearing-houses for the disposal of the patients. The present system of hospital finance is out of date and must be adapted—without imperilling the voluntary principle—to present-day requirements. In these things, he suggests, the history of the Bellahouston Hospital would well repay study.

## THE APPRAISAL OF PUBLIC HEALTH WORK.[1]

THE handsome volume issued by the American Child Health Association embodies an important contribution to public health literature, for it gives the details, with abundant examples, of a method of measuring public health activities which enables the relative position of any sanitary area to be contrasted by means of a single numerical marking with that of other areas. It is significant of a sound view of the intimate relation between child health organisation and public health organisation as a whole that the health survey of 86 cities embodied in this volume is made by a staff of five hygienists on behalf of the American Child Health Association. The outstanding results of the survey show that while in each city some organised effort was being carried on for bettering the health of children, the amount on an average was not more than half what might be expected in a reasonable health programme. The cities whose experience is thus summarised had a population at the last American census ranging from 40,000 to 70,000. They were scattered over 31 States, and may be regarded as representing all sections of the country.

Some of the results of the survey may be briefly stated. In less than half of these cities was a whole-time officer employed, in 22 of the cities the health officer was non-medical, and in only two had he a public health degree. The salary for whole-time health officers averaged £700. We learn that the utilisation of the vital records of births and deaths in revealing the state and trend of health is not common practice, though some cities obtained full marks while others obtained none under this heading. The average marking for the 86 cities was highest in elementary sanitation, next highest in laboratory work and in infant hygiene; vital statistics, venereal disease, tuberculosis, school hygiene, communicable diseases, prenatal hygiene, pre-school hygiene, and popular health instruction following in descending order of excellence, the average marking for the last-named item being only 21 per cent. of the marking for a full programme. The chief interest of the report lies, however, in its suggestions of possibilities of quantitative assessment of the relative position of various communities in respect of public health administration; and especially in the proposal to summarise the relative position of each community by means of a final comparative figure. The history of progressive effort to arrive at this result is an excellent example of organised team-work, in which the American Child Health Association has coöperated with the American Public Health Association, the final scale of marking adopted in the present volume having been fixed at a conference of representative health officers.

The appraisal form adopted in this investigation is as follows:—

| | | |
|---|---|---|
| Vital statistics | | 60 |
| Communicable disease control | | 175 |
| Venereal disease control | | 50 |
| Tuberculosis control | | 100 |
| Health of the child— | | |
| Prenatal | 75 | 350 |
| Infant | 75 | |
| Pre-school | 50 | |
| School | 150 | |
| Sanitation— | | |
| Sanitary inspection | 20 | 175 |
| Food and milk control | 75 | |
| Water | 40 | |
| Sewerage | 40 | |
| Laboratory | | 70 |
| Popular health instruction | | 20 |
| | | 1000 |

Doubtless this marking will be modified in the light of experience, and appreciation of its value must necessarily depend on the details under each heading, which cannot be given here owing to considerations of space. It will be noted that the appraisal is not based on money expended or on personnel employed, as this may represent resources more than performance. Nor is it based on mortality or sickness rates; for it is conceivable that a high rate in one area may be associated with better public health work than a low rate in, let us say, a dormitory outflow from an industrial town. In the form typical activities susceptible of definite and quantitative measurement are selected—e.g., number of children at instructive clinics, physical defects of school-children detected and treated, number of cases of tuberculosis hospitalised, laboratory tests made, and so on. These and similar activities receive a weighting, as partially indicated in the above table; and doubtless opinions may differ as to the relative markings adopted. The importance of an unbalanced marking evidently can be minimised by stating the results for each city in detail; and a chief gain from such an investigation would be the possibilities of aggregate and of detailed comparison with other communities. For tactical reasons individual markings are not given in this volume; but in communicating local results to the health officer of each city he is informed of the details of the local marking. The total aggregate marking evidently has a high value, just as has the expectation of life given by a carefully constructed life table; but alone it can give only the *vue toute ensemble;* and it needs to be supplemented by a statement of marking for individual items, just as in a life table it is necessary to know also the probabilities of life and death at each year of age or at each quinquennial period of life, if a complete picture of the vital statistics summarised in the life table is to be obtained, and if special attention is to be concentrated on effort to diminish excessive mortality at any one period of life.

The appraisal form can be made the means for valuable educational work. It can be used to secure additional expenditure on needed public health work, as a pointer showing in what directions improved administration is called for, as a summation of an annual survey of work, and as a means of arousing and maintaining public interest in the work of the health department. It is fully realised that such an appraisal form can have only a partially scientific basis, as judgment of the relative value of various health activities must vary with local circumstances and with increasing knowledge. But, although this is so, we welcome this volume as embodying an important contribution to public health literature, and as pointing the way to a rational method of comparing public health work in different communities, and, above all, of stimulating to better and more extensive work wherever this is required.

## GLYCOSURIA AND LIFE ASSURANCE

RECENT letters in our columns[1] have raised the question of the correct attitude of the life insurance office to clients whose urine contains a copper-reducing substance. Formerly it was thought that such a substance must be dextrose and therefore that the patient had diabetes mellitus. The recognition that the urine may contain other copper-reducing substances has led to more careful investigation. Even if the copper-reducing substance be dextrose, this is not sufficient to prove that the patient has diabetes mellitus and insurance offices who do no more than this test are not dealing quite fairly by their clients. It is now recognised that the blood-sugar is not constant throughout the day, but may rise as high as 0·18 per cent. after a carbohydrate meal. The blood-sugar in healthy persons has usually returned to normal after one to two hours, and unless the blood sugar rises above the level of the threshold of the kidney for sugar none can be detected in the urine by ordinary tests. The threshold of the kidney is set at 0·16 or 0·19 per cent. in the great majority of persons but it may be either higher or lower than this level. If it be lower, sugar may be present either after each meal or throughout the day, depending on the level of the threshold. Patients who have a normal sugar tolerance, but have a lowered kidney threshold for sugar are said to have a renal glycosuria. In the past these patients have been diagnosed as having diabetes mellitus, but this mistake should no longer be made. Admittedly the condition has not long been recognised, but there are some patients whose blood sugar curves have been under observation for over ten years, and whose condition has not undergone any change. There does not seem any reason why such persons should not be accepted at ordinary risks by the insurance offices. Some offices, it appears, are already doing this, but others either refer the patient to his medical attendant or defer the examination for a short period. In the light of our present knowledge this attitude does not seem correct. It would be an advantage to such a client if he (or his medical attendant) were told that he could not be accepted until his sugar tolerance had been proved normal by careful tests. If the blood-sugar curve was absolutely normal, the patient could well be accepted at ordinary rates. If it was not quite normal the patient should be deferred for a period of three months and then re-examined. Such a procedure entails a good deal of work, but the results should go far to remove any grounds for criticism of insurance offices.

## THE VALUE OF CARDIAC AUSCULTATION

IN the mind of the public the doctor is as inevitably associated with the stethoscope as is the cobbler with his last or the mason with his trowel. And the necessity of this conjunction is apparently felt almost as widely in the ranks of the profession itself, for we recently met an obstetrician who held that it was as futile for a physician to be without a stethoscope as for an accoucheur to be without forceps. To all those believing in this necessity the words of Dr Otto May, in his address to the Assurance Medical Society printed in another column, will come as rank heresy. "I say," he writes, "in all seriousness, that it was a bad day for life assurance when the stethoscope was first applied to the heart, that it has done more to confuse the issues between proposer and company than most of us can realise. Conceive, if you can, the enormous number of perfectly good lives rejected, and, what is worse, made unhappy and invalided, by the discovery of a perfectly harmless murmur'! Conceive, on the other hand, the number of thoroughly bad lives accepted as a result of the examiner's acceptance of the stethoscope as the practical arbiter of the heart's condition — no murmur therefore a good heart.' I repeat that on balance, the harm done, not only to life assurance, but to medicine generally, by the auscultation of the heart, immeasurably outweighs the good." These are very strong words, but whether we agree with the writer's conclusions or not there can be little dispute concerning his facts, of which the most serious is that healthy people are constantly led towards a permanent neurosis by the discovery of some peculiar but unimportant cardiac sound. The same result was produced during the war, when many thousands of healthy men were rejected for military service for the same reason, and it is unhappily true that once a man believes his heart to be unsound he will seldom be dissuaded even by the efforts of many cardiac specialists. But, accepting this, would we be right in rejecting the use of the stethoscope on the heart by students? Surely not. There is no reason to reject this most useful instrument in cardiology, because for a considerable period after the interpretation of murmurs had first been attempted an exaggerated value was placed on their importance by clinical teachers. This is a natural sequence of all medical discoveries and it may well be that reaction therefrom may be pushing modern opinion too far in the other direction. In France, as in many European countries, the stethoscope is still used with less frequency than in our own; but it is doubtful whether the general knowledge concerning the essentials of cardiac examination is greater abroad than in Great Britain. No doubt the foreign student will emphasise the evidence obtained by his eyes and fingers where our own will tend to exaggerate that given by the stethoscope, but the well trained and intelligent student will, in all countries, have learnt to obtain a wider series of facts from which to draw conclusions. In the next paragraph of his address Dr May gives deserved praise to the advance in knowledge which has followed the discovery of the significance of various types of cardiac irregularity. But can it be said that a practitioner who condemns a patient on account of a simple systolic murmur at the apex, will not make equally grave mistakes when confronted with some marked but benign type of cardiac irregularity? It is true that here again mistakes are frequently made by the inexperienced, but they are largely due to the fact that the detection of slight physical signs, whether by the use of the eye, the fingers, or the ear, or by any instrument which aids these senses, can only be arrived at after years of intelligent study. A house physician recently complained of the number of gastric cases admitted to his wards. "What is the interest of a gastric ulcer," he said, 'you can't listen to it!'" For such melomaniacs there is scanty hope, but we believe that assurance authorities may reasonably expect to see a steady improvement in diagnostic and prognostic skill as regards cardiology, without the abandonment of the physician's silent friend.

## GROUP STETHOSCOPY

A FORM of multiple electrical stethoscope, presented to the Royal Free Hospital, was recently described by Dr Jenner Hoskin in our columns.[1] A similar instrument was demonstrated to the Faculty of Medicine in Paris by the Dean Prof. Roger, and Drs. Le Mée, Hélie, and Rist. The apparatus was devised by the Western Electric Company, of America, and loaned to Dr Le Mée, who, with Dr. Hélie visited the United States to represent French medicine and promote Franco American medical relations. This apparatus, appearing for the first time in France, permits at least 600 persons to hear normal and abnormal cardiac and pulmonary sounds by means of numerous receivers to which stethoscopes are attached. The sounds are reinforced microphonically and also produced by a loud speaker. They are heard preferably with the stethoscope since the general amplifier does not reproduce them so exactly. The apparatus [illegible] The periods or frequencies of cardiac and pulmonary sounds range from 0 to 11[illegible] vibrations [illegible]

---

[1] THE LANCET Dec 19th, 1925 p. 1307, Jan. 2nd, 1926, p 48, and the present issue

[1] THE LANCET, 1925 [illegible]

For normal cardiac sounds the range is from 0 to 130, while different pathological sounds have ranges, respectively, of 130 to 400, 400 to 650, and 650 to 1100 vibrations. Sounds not within the ranges mentioned are automatically excluded. For example, fœtal heart sounds heard during labour are not accompanied and obscured by cries uttered by the parturient woman. Again, sounds of any range desired, of those mentioned above, may be minutely studied by excluding sounds of other ranges. These modalities are obtained by means of so-called "filters," which may be switched into circuit as desired. Some 250 persons present at the demonstration in Paris were all able to hear the sounds thus amplified and transmitted from normal human subjects, from cases of various types of cardiac and pulmonary affections, and from the heart-beats of an anæsthetised dog. Very complete illustrative diagrams aided materially in the clear interpretation of the sounds. The apparatus, already considerably used in the United States in the instruction of medical students, may also be utilised for deliberate clinical study, photographic representation of cardiac and pulmonary sounds, and the preparation of gramophone records for permanent record of interesting cases or for diagnosis at a distance. The apparatus costs about 60,000 francs.

WE regret to announce the death at Glasgow on Jan. 2nd of Prof. J. G. McKendrick, M.D., F.R.S., who occupied the Chair of Physiology at Glasgow from 1876 to 1906. We hope to publish later a short account of his life.

THE death of Prof. Edward Granville Browne, M.B., F.R.C.P., occurred at Newcastle-on-Tyne on Jan. 5th. Prof. Browne was a Fellow of Pembroke College and was Sir Thomas Adams's professor of Arabic in the University of Cambridge.

ON Jan. 5th the Prince of Wales received the honorary diploma of the Society of Apothecaries. The presentation was made at St. James's Palace by the Master of the Company (Dr. T. V. Dickinson), who was accompanied by Dr. A. Hepburn, Dr. R. Whiteside, Mr. Samuel Osborn, and Mr. Bingham Watson (Clerk). The diploma is contained in a casket of silver and shagreen.

DURING the last few months the Secretary of State for Dominion Affairs has foreshadowed improvements in the Colonial Medical Service which, it was hoped, would prove a definite step forward in public health policy. The conditions now announced for service both in East and West Africa have certain desirable features in regard to future tenure, but we lack as yet the assurance that the liberty of existing practitioners to private practice will be respected. Moreover, it would be a distinct hardship for officers engaged on the understanding that they were to serve in one area now to be transferred to another according to the exigencies of the Service. We shall be glad to learn that the new regulations sufficiently safeguard existing agreements.

## INDEX TO "THE LANCET," VOL. II., 1925.

THE Index and Title-page to Vol. II., 1925, which was completed with the issue of Dec. 26th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers wishing to receive the Indexes regularly as published should indicate this desire.

DIPHTHERIA IN WALES.—In the colliery village of Bryn, Port Talbot, owing to an outbreak of diphtheria—about 30 cases—the school has been closed for three weeks. The accommodation at Port Talbot Isolation Hospital is overtaxed. In the Amman Valley, Carmarthenshire, diphtheria is also prevalent, and several deaths are reported.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLV.—THE TREATMENT OF HUMAN ANTHRAX.

HUMAN anthrax has gradually become much less prevalent than it used to be, at least in the civilised parts of the world. The slight increase observed in many countries during the Great War did not prove of a lasting nature. In many large European countries, including Great Britain, the number of cases per year nowadays hardly reaches 100, though in Russia it went up to 13,000 cases in 1924. The causes for this gradual disappearance are not far to seek. Anthrax is primarily an animal disease, and as a result of Pasteur's fundamental work, preventive inoculation of susceptible animals has practically stamped out the disease in many countries. Imported dead material (skins, hair, wool) has thus become the only source of infection.

These facts are of importance in connexion with the treatment of human anthrax in two respects. First, in view of the comparative rarity of the disease few practitioners can acquire first-hand knowledge of its manifestations, and the rest have to rely on text-book information for the diagnosis of a disease where speedy recognition is an essential factor in treatment. Secondly, a practitioner can hardly be expected to equip himself for the specific treatment of a disease which he is very unlikely to encounter. The specific serum is not always easily obtained in out-of-the-way places. A reliable chemo-therapeutic method of treatment such as that described below is therefore of considerable value.

The mortality of human anthrax seems to vary, but it is far from negligible. Most statistics do not differentiate between pulmonary and cutaneous anthrax. The majority of cases fortunately are cutaneous anthrax, but even for these one must assume a mortality of about 10 per cent., and this includes treated and untreated cases. It is futile to discuss "virulence" and "disposition" in this connexion, since no information about these points is forthcoming.

### *Diagnosis.*

As F. W. Eurich has pointed out, the early diagnosis of pulmonary anthrax is particularly difficult. E. Fraenkel has recently stated that primary lesions in the trachea and at the bifurcation are the rule in such cases, but inspection of these regions will rarely be practicable. Eurich notes that the pictures of cutaneous anthrax in present-day text-books represent late stages, and that the first symptoms of cutaneous anthrax do not suggest anything like "malignant pustule." However, most patients reach the doctor only when the pustule is well developed.

Microscopical diagnosis is usually described as rapid and easy, but in practice one generally has to be satisfied with a clinical diagnosis. Bacteriological confirmation is, of course, highly desirable. Very extensive œdema around a comparatively small central lesion will suggest anthrax, but only if that possibility is borne in mind. Here circumstantial evidence (occupation, dealings with dead cattle, a new shaving-brush), or in other words, a good case-history, is of at least as much importance as mere clinical appearances.

### *General Measures.*

Specific prevention of human infection seems indicated for persons engaged in specially dangerous occupations, but apart from injections of the specific serum in cases where infection has probably already occurred, no attempts in this direction seem to have been made. As regards the treatment of human cases of anthrax, the surgeon's day has passed. The cautery is no longer used, and it is generally recognised that incision or excision, short of amputation of a limb, does more harm than good. An exception must be made for those (perhaps hypothetical) cases where the disease is really in its very first stage, and the microbes clearly have not yet made their way into the deep tissues beyond the reach of the surgeon's knife. In all other cases, that is, practically always, the local treatment should consist of rest, and the application of a dressing soaked in a mild disinfectant. Rest can, as a rule, be secured by sandbags. It follows that an anthrax patient should be in bed, fever or no fever, for the affection always tends to become a septicæmia, and this complication should be avoided as long as possible

### *Specific Treatment: Serum.*

The orthodox specific treatment of anthrax is by means of anthrax serum, with which the names of A. Sclavo, E Marchoux, and G. Sobernheim are associated. Its method of action is unexplained, and it has not been shown to possess bactericidal properties, at least not *in vitro* It certainly contains agglutinins and bacteriotropins, and the presence of antitoxins seems likely. The serum is produced in animals (sheep, asses, or oxen) by means of injections of attenuated anthrax virus, followed by injections of virulent cultures Good results have been observed with this serum in many cases, especially by Sclavo At the 1924 session of the Health Committee of the League of Nations various members testified to the excellent results obtained by the use of anthrax serum in their respective countries. It has proved effective even during the last stages of the disease (D Ottolenghi) In view of these results the members of the Committee suggested that the time had come to undertake investigations for its titration. The exact value of anthrax serum is difficult to gauge where so little is known about the virulence of the infecting material, and the standardisation of the serum has not yet been undertaken. It may be hoped that the keeping qualities of the serum, especially under tropical conditions, will be included in the projected investigations.

The application of the serum, when available, is certainly indicated in all stages of the disease. It must be remembered that good results can only be expected from really large doses. At least 30 c.cm. should be given the first time, preferably intravenously. The following daily doses may then be made smaller, and can be given subcutaneously. Acting on these principles Sclavo succeeded in reducing the mortality, calculated from a large number of cases, from 24 to 6 per cent. Some recent authors advocate very large doses, and these in combination with excision. From the nature of the disease it is quite likely that cases will occur where serum is not available, or at least not readily available, in sufficiently large quantities. Even then surgical measures should, in my opinion, be avoided, for there are other efficacious measures (see below) Certain curious observations by R. Kraus, working in South America, have attracted some attention. He claims that the serum of normal, untreated sheep and cows possesses protective and curative properties against anthrax infection, which are quite comparable to those of the specially prepared serum. These observations, when put to the test by others, have not been confirmed, but quite recently Kraus has again maintained that his observations, based both on clinical and laboratory experience, were correct.

### *Chemical Treatment.*

Efforts to control anthrax infection in man with injections of such chemical preparations as auramine or argochrom have not yet got beyond the discouraging stage of "encouraging results."

*Salvarsan.*—Treatment with neosalvarsan (or substitutes) was inaugurated by F Becker. Although splendid results were obtained by him, and shortly afterwards by others, this form of treatment has not come into general use, nor has it received much encouragement from writers of text-books. In medical journals may be found an occasional report on the excellent results obtained through the use of this drug. Eurich only advises its use when serum fails or is unobtainable Quiet recently O M. Rovsing has again emphasised the virtues of neosalvarsan, but the drug has not received the attention which it deserves. In 1918 I introduced this form of treatment into South Africa. It was then used in two cases, and these not only survived their infection, but made a particularly rapid recovery. This was all the more striking because in the preceding year, working in the same district, I had attended two similar cases, and in spite of surgical measures both were dead within a week. It must be added that anthrax serum was not then, and probably is not now, available in South Africa, or at least not readily available.

During the last few years, at the Pretoria Hospital, we have had a good opportunity of testing the value of the salvarsan treatment. Since 1921 all cases of anthrax entering this hospital have been treated exclusively with salvarsan. We now have records of a series of over 40 consecutive cases, and there has not been a single death It must be admitted that we have had no cases of pulmonary anthrax. Some cutaneous infections, however, were very severe, and one or two were admitted in what seemed to be a moribund condition. A striking instance was that of a youth, employed at the Onderstepoort Veterinary Research Laboratory, who against all warnings had been careless with the very virulent anthrax cultures grown in that laboratory. A huge sore developed on his lip, and he arrived at the hospital in a septicæmic condition. A few injections of neosalvarsan saved even this patient.

As a result of this series of successful cases the Secretary for Public Health of the Union of South Africa has sent a special circular to all district surgeons of the Union, in which their attention was called to the salvarsan treatment. This led to its more extensive use, with, as far as we know, complete success. It is noteworthy that during these same years a few deaths from anthrax have been recorded in the Union and that in these cases salvarsan was not tried.

### *The Routine Followed.*

At the present time the routine treatment of anthrax at the Pretoria Hospital is as follows. Directly after the suspected patient is admitted, smears are examined from the sore, preferably from the vesicles. In this way a diagnosis can be made with a probability approaching certainty in a few minutes. In doubtful cases this has, of course, to be confirmed culturally. The next process is an intravenous injection of 0·6 g. to 0·9 g. neosalvarsan, the exact dose depending on the condition of the patient. The worse the patient appears to be, the bigger the dose. Anthrax patients apparently stand large doses of salvarsan quite well. The patient is put to bed, a mild antiseptic dressing (weak formalin solution is very suitable) is applied, and the part is immobilised. The injection of salvarsan is repeated the next day. A rise of temperature is a common result of the injections. Some cases require a third injection on the fourth day of treatment, but this is exceptional. As a rule the symptoms, especially the œdema, show definite improvement on the third, sometimes on the second day of treatment The temperature comes down to normal in five or six days, the necrotic part drops off, and generally a surprisingly small scar is all that remains.

The salvarsan treatment of anthrax has never failed us yet, although its theoretical foundation may be lacking. The obvious advantages are that it requires no special outlay nor preparations, that it can be applied at a moment's notice, that it is safe, sure, and quick, and that the lesions heal with a minimum amount of disfigurement.

## A DISCUSSION ON FRACTURES IN THE NEIGHBOURHOOD OF THE ANKLE-JOINT.[*]

### II.—THE OPERATIVE TREATMENT OF ANKLE FRACTURES.

By W. H. Trethowan, F.R.C.S. Eng.,
ORTHOPÆDIC SURGEON, GUY'S HOSPITAL, LONDON.

My remarks are directed to the classification, causation, and treatment of malleolar fractures. From none of these aspects is the subject so difficult as the careful and academic survey of the opener of this discussion would suggest. For the purposes of teaching and formulating treatment a simple and clear-cut idea of the one or two principles involved, and the definite types of fracture that occur, would seem to be desirable.

For simplicity, accuracy, comprehensiveness, and practical applicability there can be no better classification than that of Arbuthnot Lane, who, 25 years ago,[†] was the first to group the various malleolar fractures in such a way that their relationship to one another could easily be understood. Further, he made clear beyond doubt the mechanics of their production, and—the greatest principle involved—he emphasised the importance of perfect anatomical reconstruction as a prime necessity for the complete restoration of function. Lane, with his grasp of skeletal mechanics, is one of the greatest orthopædic surgeons we have had, a fact which can be appreciated only by the few who will look beyond the details of "plates and screws" for the general principles he postulates. Lane's conception of "traumatic" or "mechanical" arthritis resulting from skeletal mal-alignment, occurring as well in postural, occupational, and pathological conditions, as in trans-articular fractures, and causing the eventual breakdown of function of a joint, is one of the most important factors in determining methods of treatment in bone and joint surgery.

ARBUTHNOT LANE'S CLASSIFICATION OF ANKLE FRACTURES

Lane's classification of ankle fractures.

The recent comprehensive work on ankle fractures by American writers, referred to by the opener of this discussion, adds nothing to what has already been done by Lane, but serves rather to cloud a subject already clarified to simplicity itself. Lane classified the ankle fractures according to the degree of deformity, and showed there were only five fractures, all typical and constantly occurring (Fig. 11).

(1) *Abduction Fractures* (eversion, or valgus).—Three degrees, according to the displacement.

First degree: Oblique (torsion) fracture of the fibular malleolus. Line of infraction runs from above and behind downwards and forwards. Inferior tibio-fibular ligament remains intact. No displacement.

Second degree: Fracture of fibular malleolus as in the first degree, but with displacement of malleolus (and with it the astragalus and foot) outwards and slightly backwards. Fragments tend to telescope on themselves, causing shortening of the fibula. The astragalus is tilted, its outer and upper edge tending to lie at the spot where the tibia and fibula meet (lower end of inferior tibio-fibular ligament). As permitting this outward displacement of the foot in the second degree fracture, either the inner malleolus is cracked transversely at its base, by traction, or it is left intact, and, instead, the internal lateral ligament of the ankle-joint is torn through. Thus occur two subtypes of the second degree fracture. A third subtype is occasionally seen, when the fibula breaks *above* the inferior tibio-fibular ligament. This ligament itself gives way, and the lower fibular fragment becomes definitely separated from the tibia. To this third modification of the second degree fracture the term "Dupuytren's fracture" is occasionally given.

Third degree: To the malleolar fractures characteristic of the second degree is added a fracture of the posterior edge of the lower end of the tibia. The astragalus, with the foot, slips backwards, and the clinical picture produced is that of partial or complete dislocation of the ankle-joint. There may also be some outward displacement, as in the second degree, but the posterior displacement of the foot is the chief feature.

(2) *Adduction Fractures* (inversion, or varus).—Two degrees, according to the displacement.

First degree: There is a transverse fracture of the external malleolus at its base, at the level of the lower end of the tibia, the malleolus being broken by a "pull" upon it as the original violence tends to displace the foot inwards. The internal malleolus is broken obliquely vertically at its base by a "push" thrust of the displacing foot. But the fragments are not displaced, and the astragalus remains in perfect relationship with the lower end of the tibia.

Second degree: This differs from the first degree only in that the astragalus, with the foot, and also both malleoli, are displaced internally.

The method of production of these fractures is easily comprehended. The *abduction* fractures occur on forcible inward rotation of the abducted lower limb, aided by the momentum of the swinging trunk and a partly flexed knee, when the foot is firmly fixed on the ground. The foot is "torsed" off the leg by a violent external and valgus twist relative to the leg. The amount of displacement is merely a matter of the degree of the original fracturing force. If there be added a forward thrust on the lower limb (and therefore backwards on the foot) when, as in slipping on the edge of a step or on some inclined surface, the foot be also forced backwards, we get the backward thrust in addition to the external twist on the foot, and the characteristic third degree fracture results. Occasionally, in a purely backward thrust upon the foot, the posterior border of the lower end of the tibia may be broken off, permitting backward dislocation of the foot, but without fracture of the malleoli. This lower tibial fracture has recently been re-observed and re-described, but long ago Lane described it as an essential part of the third degree displacement. The *adduction* fractures result from a forcible inversion of the foot, and are further degrees of the violence which commonly produces the usual type of sprained ankle.

The mechanics of the production of abduction fractures of the ankle are the same as for many other injuries of the lower limb resulting from indirect violence. It is a matter of accident that the line of fracture actually passes through the ankle-joint, rather than occurring higher up in the limb. The line of fracture is relatively higher in the fibula, passes through the ankle-joint, and is lower on the inner side, where it passes through either the inner malleolus or the internal lateral ligament. In spiral (i.e., indirect) fractures of the leg bones the fibula is nearly always broken at a higher level than the tibia. This oblique line of cleavage occurs at different levels in various cases of fracture of the tibia and fibula. In still other cases the same violence may result, instead, in damage to the internal lateral ligament of the knee-joint and semilunar cartilage derangement; or, again, in oblique fractures of the femoral shaft, or in fracture of the neck of the femur in more elderly subjects.

---

[*] The introduction to the discussion, by Mr. Harry Platt, appeared in the last issue of The Lancet.

[†] The Operative Treatment of Fractures, Med. Pub. Co.

FIG 12

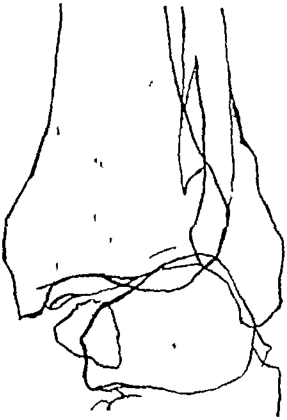
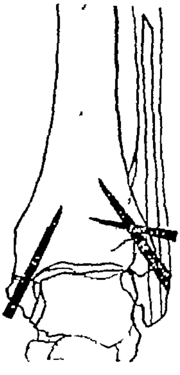
FIG 13, A.



Third degree abduction fracture of six months' duration. Malunion.

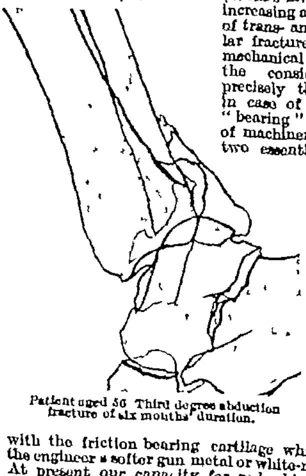
FIG. 13, B.



Patient aged 50 Third degree abduction fracture of six months' duration Intramedullary autogenous graft to reconstruct fibula. Three ivory pegs to sustain both malleoli.

The gravest type of *fracture* is that involving a joint, where a part or the whole of one bearing surface *is* displaced relatively to the other The resulting permanent disability is proportional to the displacement, and to the age of the patient—since the capacity for skeletal adaptation (Wolff's law) lessens with increasing age. Treatment of trans- and intra-articular fractures is a purely mechanical problem, and the considerations are precisely those applying in case of damage to a "bearing" in any piece of machinery There are two essentials: (1) fair and even bearing of the mutually adapted moving parts must be restored, (2) the bony ends (representing the steel foundation in an inanimate machine) may at times require to be 're bushed'' with the friction bearing cartilage which represents the engineer's softer gun metal or white-metal bearings At present our capacity for re-bushing a damaged joint is very little. In inaccurate reposition of the mutually apposed and intricately shaped bearing surfaces of a joint damaged by fracture, the friction is not evenly distributed is localised, and is excessive. As the deranged engine bearing would run hot, grate, squeak, become restricted in movement, and finally seize up or melt, so *the injured* human bearing responds with exactly the same symptoms.

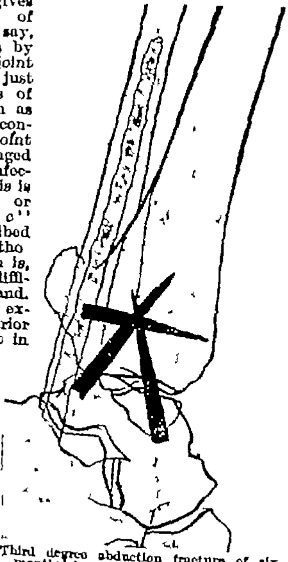
FIG 14, A.



Patient aged 50 Third degree abduction fracture of six months' duration.

Failure accurately to re-appose related joint surfaces gives *permanent* loss of efficiency—as we say, disability — thus by excoriation of joint surfaces, giving just the same signs of inflammation as occur on the continued use of a joint irreparably damaged from toxic or infective causes. This is "mechanical" or "traumatic" arthritis, as described by Lane. The pathology of malunion is, therefore, not difficult to understand. Who has not examined the interior *of an ankle-joint* in the case of an old malunited Pott's fracture? Without accurate reconstruction of the ankle-joint in malleolar fractures the onset of traumatic arthritis is inevitable sooner or later, leading to lowered efficiency. Posing as

FIG. 14, B.



Third degree abduction fracture of six months' duration. Intramedullary autogenous graft to reconstruct fibula. Three *ivory pegs to* sustain both malleoli.

surgical mechanics, we must be able to reconstruct a joint accurately. This is the only principle involved. The method is a matter of detail, according to the needs of the case or the capacity of the surgeon-mechanic; it may be manipulative or operative. The point of view I put forward is that, granted accurate anatomical reconstruction is of vital importance, in many cases reduction by manipulation alone, to a degree of accuracy sufficient to ensure against the gradual onset of disability from mechanical arthritis in later years, is impossible. Therefore there should be a freer resort to open operative correction. This advocacy of open correction presupposes a mechanical ability, and a surgical technique beyond reproach. It is the duty of a surgeon-mechanic to be able, fearlessly and without anxiety, to deal with a human joint as intimately as the mechanic does with a machine bearing. Manipulative reconstruction in the more severely comminuted cases is on a par with trying to do a jig-saw puzzle by manipulating the pieces through the wall of a bag in which they are inaccessibly tied up. Where there is any displacement at all, even in the second degree valgus fracture with fibular malleolus alone fractured, I prefer to open up the fracture, as ensuring both the patient's complete recovery and my own peace of mind. If you elect to treat any ankle fracture with displacement by manipulative means alone, you must be careful to ascertain by skiagraphic examination that the reduction has been complete. If it is not you will have failed, and the joint is bound to break down sooner or later, from traumatic arthritis, with complaints from the patient of "rheumatism" and increasing lameness. Where no displacement exists (first degree), or when it is really corrected by manipulation, nothing more is required than the "bi-valve" plaster-of-Paris, and the application of massage within a day or two. But judging from the frequency of bad results, which we as orthopædic surgeons are so often asked to treat "with a boot," it would seem that the manipulative and plaster method in many cases meets with about the same degree of success as we might expect to attend the efforts of a motor mechanic who elected to tackle the main bearings of a car by putting plaster-of-Paris around the bonnet.

Open correction does not necessarily imply internal fixation of the fragments; this will depend on the needs of the case. Foreign material introduced for fixation purposes should be minimal. Absorptive material is preferable, but often the tension of the displaced parts necessitates the use of metal screws. I never open up a fracture without being prepared to use screws, pegs, nails, wire, sutures, or living graft, as may seem expedient. Fragments must be replaced so that they do not project and irritate the opposite joint surface. If so small as to be unfixable they are better removed. The operation for the second degree of valgus fracture is through a curved peroneal incision, behind and below the external malleolus. The fibula is re-aligned, and the lower fragment is screwed to the tibia by a 1½ to 2 inch screw driven up obliquely from the base of the malleolus, with care to avoid its passing through the outer upper corner of the ankle-joint. I prefer this single screw to a 4 to 6-hole Lane's plate on the posterior surface of the fibula. In the third degree fracture, the fibula is first re-aligned and fixed, as above. Then, by means of a long incision on the inner side of the leg, midway between the inner border of the tibia and the tendo Achillis, and curving forwards beneath the inner malleolus, the posterior fragment detached from the lower end of the tibia is fixed by one or two screws, access being between the posterior tibial artery and nerves (which are drawn forwards) and the flexor longus hallucis (retracted backwards). Finally the internal malleolus is replaced, and it may or may not require some fixation. A back splint with foot-piece is applied for two weeks. Active movements start on the third day, massage a few days later, and over the whole field when the stitches are removed in 14 days from the date of the operation. The patient may begin to take weight on the foot in four weeks from the operation. Failure to institute early movements delays the restoration of function, just as after prolonged fixation in plaster-of-Paris, and the scars may add to this tendency (Figs. 12–14, B).

With regard to fractures of some duration (malunion), the only operation that can be of any use is a complete anatomical reconstruction of the joint (see Figs. 13, A–14, B). I have reconstructed such joints up to a period of 18 months after the fracture. After two years the degree of ensuing mechanical arthritis would make the operation not worth while, and an arthrodesis of the ankle-joint, or a Syme's amputation, would be the only possible operative remedies. In these late cases the gratifying feature is the complete freedom from pain which the operation affords, although in any case operated upon after about three months from the time of the accident complete restoration of plantar- and dorsi-flexion movements is scarcely to be expected. The difficulty in these cases is the restoration of the substance of the fibula. In an abduction fracture the fibula shortens by overlapping of fragments, and even if it be cut as carefully as possible along the line of the original fracture there is bound to be a gap between the fragments when the ankle is completely reduced and the fibula re-aligned. After a trial on many methods—e.g., cutting the fibula above the fracture and grafting the gap, while leaving the original fracture intact—I find it best to cut the fibula as nearly as possible along the original line of fracture, reduce the ankle dislocation, re-align the fibular fragments, and then put an intramedullary graft, 5 inches in length and taken from the crest of the same tibia, and filed off to form a firm cylindrical bony peg of $^{3}/_{16}$ to ¼ in. diameter, up through the central canal of the fibula, after drilling out the central axis of the external malleolus and the shaft of the fibula for several inches above. The graft is driven up from below, from the tip of the external malleolus, the fibular fragments being held in correct position meanwhile. The gap in the fibula is thus bridged by autogenous living bone, and is gradually obliterated and the bone consolidated. An ivory peg similarly used seems to encourage no restoration of the fibular gap. The replacement of the fragment from the back of the lower end of the tibia, and of the inner malleolus, can be procured through an incision along the postero-internal aspect of the leg and ankle, as in the operation for the recent third degree abduction fracture. Here a simple fixation, by wire nail or ivory peg, will suffice.

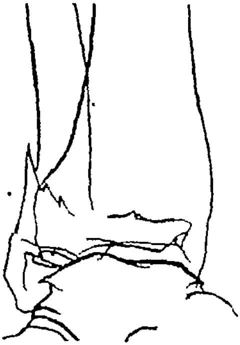
The "classical" operations of the past age, for malunited Pott's fracture, are useless, as they ignore the only mechanical consideration—viz., that the bearing surfaces of the lower end of the tibia and upper aspect of the astragalus shall be accurately and horizontally restored in correct mutual relationship. In this condemnation come malleolar and supra-malleolar osteotomies. It is true they may give a superficial cosmetic result, but their mechanics will not bear examination. As Lane has always maintained, "restore the fibula in its alignment and length." The rest "shall be added unto you."

## III.—THE OPERATIVE TREATMENT OF ANKLE FRACTURES.

By H. A. T. Fairbank, M.S. Lond., F.R.C.S. Eng.,
SENIOR ORTHOPÆDIC SURGEON, KING'S COLLEGE HOSPITAL.

It seems to me that the chief point that calls for discussion in Mr. Platt's most admirable opening paper is the amount of displacement of the fibular fragments in relation to the necessity for operative reduction and fixation. For the sake of argument I show slides of a case with the usual oblique fracture of the fibula, but without obvious displacement of the astragalus and without fracture of the tibia (Fig. 15). In such a case, when young or middle aged, I should certainly operate. Greater difficulty is experienced in maintaining reduction than in the actual correction of the deformity. Even when the position of the astragalus is perfect, the slightest tilt of the lower fragment of the fibula spoils the fit of the bones forming the ankle joint, and any instability in the joint means grave risk of arthritis and disability. I have seen large numbers of such cases who continued to have pain, &c., for many months and years. Even with an open wound the difficulty often experienced in holding the fragments in perfect position while a plate and screws are inserted is very striking Absolute perfection in the replacement is essential, as without it the fit of the joint will still be imperfect. When a case with minor displacement is only seen four or five weeks after the accident, operation is often inadvisable because the callus increases the difficulty of obtaining the perfect restoration of the fragment which, in such cases, alone justifies treatment by the open method If I understood Mr Platt correctly, he said that the average time that elapsed before the patients in his series were finally discharged, was six months, and he was disappointed with the results in quite a number of those. But when these cases were investigated after a further period of several months had elapsed, he was gratified to find many of those discharged with imperfect results had recovered and were at work. Surely this statement might be used as an argument in favour of the more extended use of operative methods which would lead to reduction in the length of after-treatment necessary.

FIG. 15.



Oblique fracture of fibula. Type of fracture suitable for operative reduction

Lastly, I should like to call attention to those cases of partial or complete separation of the lower epiphysis of the tibia resulting from forcible abduction. If complete, the fibula often gives way transversely in the lower third. Perfect reduction is often difficult without open operation. When the separation is incomplete, growth at the epiphyseal line is interfered with, and a progressive varus deformity not uncommonly results.

## IV.—MANIPULATIVE TREATMENT.

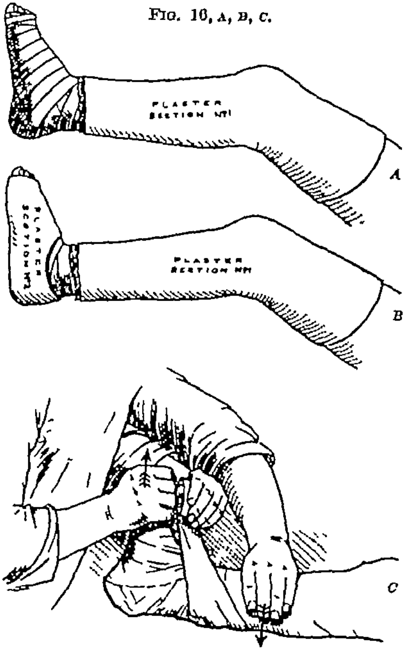
BY W. A. COCHRANE, M.B, F.R.C.S. EDIN,
ASSISTANT SURGEON, EDINBURGH ROYAL INFIRMARY

DISABILITY figures for fractures involving the different joints are readily obtained from the Industrial Board of one of the American States. In a three-year period, 1921–24, 2160 joint fractures are recorded, and of these 558 were ankle fractures. The average period of total disability was 13 0 weeks. The figures obtainable from the records of the Royal Infirmary, Edinburgh, represent a recent series of 40 cases The average period of total disability was about 15 weeks. There has been permanent partial disability in six cases. All the others have returned to their old employment. Operative treatment was not employed in this series.

I have been interested in Mr. Platt's account of the mechanism of production of the various fractures about the ankle, and the Association is indebted to him for drawing attention to the classical work of Ashhurst. It is the first account of research in this field since the days of Astley Cooper. Ashhurst's description of these cases is remarkable for the great frequency of spiral fracture of the lateral malleolus, without appreciable displacement; 60 per cent. of his series fall into this category. His classification of fractures of the ankle according to their mechanism of production is of great clinical importance. The subject is simplified by so doing and rational diagnosis and treatment made easier for the teacher and student. Another useful way of considering joint-fractures is to differentiate them into juxta-articular and intra-articular fractures. The former are situated in close relationship to the joint, but do not involve the articular surface, while the latter penetrate into the joint The juxta-articular fracture is important chiefly because of the peri-articular exudation and of the stiffness of the joint which is apt to follow if active movements and massage are not instituted early.

In the case of the intra-articular fracture, the chief consideration is the possibility, if complete anatomical replacement is not secured, of a permanent alteration in the axis of the joint. Angular deformity is the worst displacement and is responsible in many cases for a disabling traumatic arthritis when weight-bearing is resumed. The injury to the cartilage also may result in the formation of obstinate intra-articular fibrous adhesions. The recovery of function demands, therefore, that complete anatomical replacement should be the goal and that this must be followed up by early active movement. My experience has been that it is not unusual for the minor displacements to be overlooked by the practitioner. It is he and not the orthopædic surgeon who sees and treats most of the fresh cases. I would emphasise the importance therefore of teaching the physical signs of displacement very carefully to students, because it is a fact that a large proportion of these cases, occurring often in the country, are not X rayed.

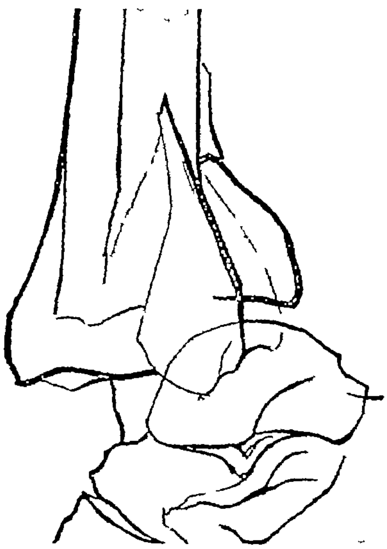
FIG. 16, A, B, C.



Illustrating method of plaster application after reduction The "three piece" plaster.

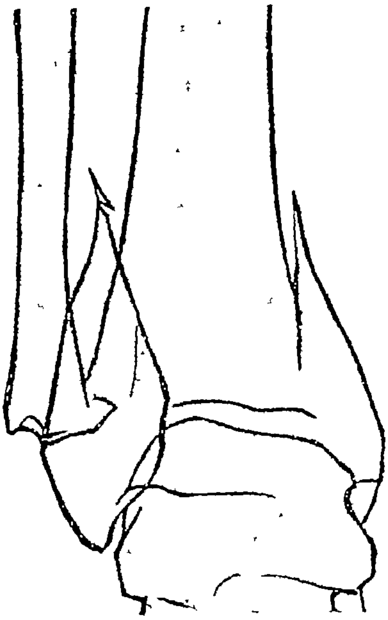
The temptation is to put the leg in a splint and to trust to massage and early movement.

FIG. 17, A.



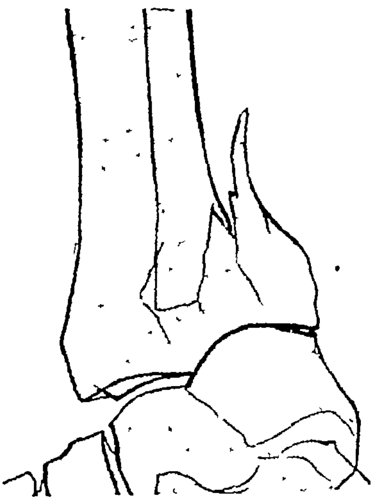
Fracture dislocation of ankle (lateral view).

FIG. 17, B.



Fracture dislocation of ankle (antero-posterior view).

FIG. 17, C.

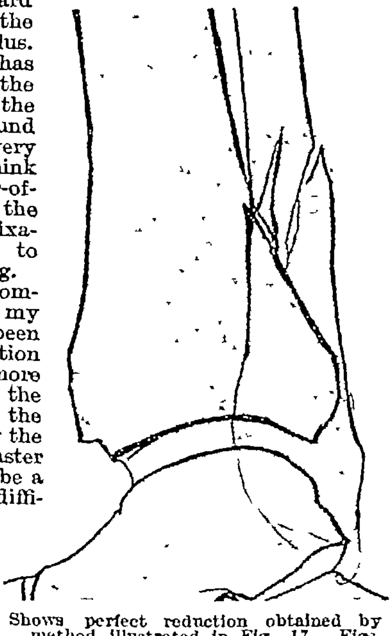


Same fracture after manipulative reduction and plaster. Displacement uncorrected.

As regards the method of reduction of a Pott's fracture, the knee should be flexed and the posterior displacement forcibly corrected, with the foot in plantar-flexion. The foot should then be forcibly dorsiflexed and inability to secure this should be regarded as indicative that reduction is incomplete. The lateral displacement should then be corrected by inward pressure upon the lateral malleolus. When reduction has been secured, the movements of the foot should be found to be free in every direction. I think that a plaster-of-Paris casing is the best means of fixation, bivalved to permit of swelling.

In the more complicated cases, my experience has been that, while reduction may be secured more or less easily, the maintenance of the reduction during the application of plaster or a splint may be a matter of great difficulty. A plaster-of-Paris casing applied in sections is often of value as being more precise and dependable. Figs. 17, A and 17, B show a fracture-dislocation of the ankle, with backward and inward displacement of the foot in relation to the leg. Fig. 17, C shows that the reduction and fixation in plaster have been unsuccessful. While the casing was being applied a momentary slackening of the hold or an alteration of the position of the surgeon's hands had allowed the corrected position to be lost. A second attempt was made. The first section of the plaster was applied from a point two fingers'-breadths above the level of the ankle to the mid-thigh (Fig. 16). The second section was applied to the foot, of the dimensions and extent of a shoe. This left the ankle free. The two casings were allowed to set. The manipulations to secure reduction were then made by grasping the two casings. An assistant then united the two plasters by the turns of a third bandage. Fig. 18 shows that reduction had been secured by this means. The final result was excellent, the patient walking as well as ever in three months' time.

FIG. 18.



Shows perfect reduction obtained by method illustrated in Fig. 17. Figs 16–18 are taken from the *British Journal of Surgery*, October, 1924.

## V.—REMOTE RESULTS OF TREATMENT.

BY S. T. IRWIN, M.CH. R.U.I., F.R.C.S. EDIN.,
HONORARY SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST.

I HAVE assembled statistics from the records of the Royal Victoria Hospital, Belfast, during the two years 1923–24. The figures are based upon a consideration of all the cases of fracture at the ankle admitted to the wards of the hospital during these years. They have been treated in the various surgical wards to which fractures are admitted as emergency cases on the "take-in" day. There were during the two years a total of 75 cases. These were communicated with by letter and invited to answer a number of questions, the main object being to find out whether or not the patient had returned to work. Where no replies were received the addressees were visited. In this way 62 cases were located out of a total of 75, and of these 62 cases five were found not to be working and two were dead from causes unconnected with the injury. Of the five who were out of work one had worked until he developed an ulcer of the leg. This case will be referred to later.

The important questions to decide were: (1) whether or not the patient was at work; (2) the total period of incapacity. It was not possible in the time to go fully into other questions, such as whether the patient suffered pain, whether there was any deformity, or whether the patient was lame. Investigations of case-sheets and X ray films supplied the data upon which the cases were classified, it having become obvious early in the investigation that many of the diagnoses were faulty. The term "Pott's fracture" was used in the records to include a very diverse group and so, more or less, arbitrarily the following subdivisions of the fractures was made into four types.—

Type A, "*Pott's Fracture.*"—To include those cases in which there was a fracture of the fibula near the lower end associated with displacement of the foot outwards and some definite injury to the inner ankle as well.

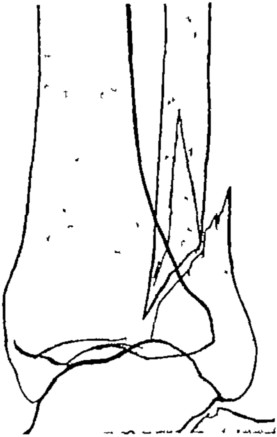
Type B.—*Fracture of the external malleolus* below the tibio fibular ligament, the internal malleolus remaining intact. No doubt this group will include some cases which upon more precise and prolonged investigation will be found to be really examples of Pott's fracture, but in none of them was there obvious displacement of the foot.

Type C.—*Fracture of both malleoli* involving the joint on both sides.

Type D.—*Various fractures* usually associated with *considerable comminution* of the tibia and fibula. This group includes two cases of "Dupuytren's fracture."

This classification was found to have certain advantages—for example, all fractures included under Type B gave uniformly good results, probably because there was no displacement of the foot; their stay in hospital was brief, the average for the whole group being just over a fortnight.

FIG. 19, A.



Pott's fracture showing gross deformity after attempt at fixation in splints. (Mr H. P. Malcolm's case.)

*Compound Fractures.*—So far as the records go only three cases are known to have been compound. All of these were able eventually to return to work, but they are associated with a very prolonged period of incapacity—one for 70 weeks and another for 104 weeks.

Taking the types in order—

1. Under Type A 30 cases occur in the records. Twenty of these were followed up and 19 were at work.

The only case of this type not at work was admitted on Christmas Eve, 1924, profoundly drunk. His age was 60. He had a wound over the inner ankle which, however, did not appear to communicate with the seat of the fracture. He was a saddler by occupation. Within the last few days he has been examined. He walks without pain, the movements of the joints are free, there is a very slight degree of valgus. Except for this and for his age there seems to be no reason why he should not do a saddler's work.

2. In Type B, fractures of the external malleolus without displacement, the records show 14 cases. All these were found and all were at work.

3. In Type C, fractures of both malleoli, involving the joint on both sides, there were 11 cases. Eight of these were found and seven were at work.

The eighth case, a young woman aged 26, was examined. The position of the foot was good; there was no obvious cause to be found for her alleged disability nor was she complaining of pain or lameness.

4. Type D. There were 20 cases in this group of whom 18 were found. Three of these were not at work.

The first was a man aged 40, whose injury occurred two years and two months ago. The fracture was 4 inches above the external malleolus with comminution of the tibia. The result of this case was anatomically bad, especially as regards alignment, there being marked adduction at the seat of the fracture, some arthritis in the ankle-joint, considerable pain, and lameness. Added to the bad alignment of this there was also synostosis between the bones above the seat of the fracture.

The second case under this type not at work was a woman aged 56, off work for one year and six months, whose fracture affected both bones complicated by the opening of the ankle-joint. The foot was in a position of equinus and there was considerable ankylosis and faulty alignment.

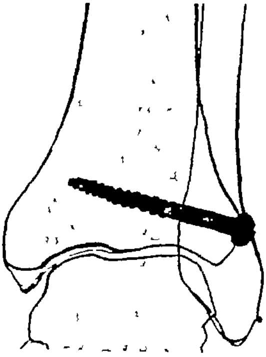
The third case in this type has worked but has had recently to discontinue on account of an ulcer developing over the subcutaneous part of the tibia. He is a young man and the accident was caused by his being thrown off a motor bicycle, the foot striking the mudguard of a motor-car with which the bicycle had collided. This man had a compound comminuted fracture at the lower end of the leg bones. All the structures behind the internal malleolus were divided. As the result of treatment he had ankylosis both of the ankle and the subastragaloid joints but comparatively free movement in the anterior part of the foot. The complication of an ulcer at the seat of one of the old wounds over the subcutaneous part of the tibia is very serious; such ulcers are prone to recur, to cause a subjacent periostitis, and it may yet result in amputation.

These figures are grouped in the following table. Excluding two cases dead there were 60 cases found.

| Type of fracture | Found. | Working. | Per cent. |
|---|---|---|---|
| Pott's | 20 | 19 | 95·0 |
| External malleolus . . | 14 | 14 | 100·0 |
| Both malleoli . . | 8 | 7 | 87·5 |
| Various | 18 | 15 | 83·3 |
| Total . .. | 60 | 55 | 91·6 |

Next the average time off work in each of the types was considered. The small number of the cases makes the results less valuable, the best average period of disability occurring in Type B, where the average is 20 weeks and the average stay in hospital 15·6 days. The second best occurs in Pott's fractures, with the average period of disability at 22 weeks. Here the figures are arrived at from the consideration of 19 cases. For the fractures of both malleoli involving the joint on both sides the period of incapacity over 7 cases amounts to 38 weeks on average. This period seems unduly prolonged, but the group happened to contain a very high proportion of elderly patients. For the comminuted fractures of the tibia and fibula over 16 cases the average period of incapacity amounted to 28 weeks.

FIG. 19, B.



Same fracture after fixation by a single screw nail.

As to the method of treatment in these cases, out of a total of 75 cases only 4 had an open operation, 3 primary and 1 secondary. The custom in the Belfast school has been to treat the majority of these fractures on a Cline's splint with anterior and posterior splints, as recommended by the late Prof. Gordon. They are usually reduced under an anæsthetic. It has several advantages: 1. It allows the leg to be treated with the knee flexed. 2. The splints being of wood allow an X ray photograph to be taken after the fracture has been set. 3. It provides for maintaining full adduction of the foot. 4. With Gordon's anterior and posterior splints both pes equinus and backward displacement of the heel are prevented. 5. Massage can be used early without risk of displacement, the limb resting on the outer splint. In a few cases belonging to Type D the Cline's splint was discarded in favour of a Thomas bed splint with Sinclair foot-piece. One surgeon prefers the use of moulded plaster-of-Paris to the Cline's splint.

A special word is necessary for the three cases who had primary operations.

The first of these was a torsion fracture of the Pott's variety with an oblique fracture immediately above the external malleolus in which it was found impossible by splints alone to maintain correction (Figs. 19, A and B). Here a long screw nail was introduced to bind the malleolus to the tibia above the level of the joint after full correction had been obtained. This nail was removed under local anæsthesia a fortnight later. The second case was a comminuted fracture, which after several attempts at re-position had failed was treated by wires encircling separately the tibia and the fibula. The third case was the compound fracture already referred to. As Mr. Platt has said, "This is not, strictly speaking, a fracture of the type which I have dealt with and therefore the fact that it was operated on can hardly be used as an argument against conservative as compared with operative methods."

The conclusions arrived at from a consideration of the 60 consecutive cases are as follows: 1. The results of conservative treatment combined with operation in specially selected cases would seem to offer an efficient method for indirect violence fractures at the ankle—in the series of 60 consecutive cases 91·6 per cent. being at work. 2. That the period of incapacity in all the cases, extending as it does to 20 weeks in a simple fracture of the external malleolus to double this period in some of the other fractures, seems to be unduly prolonged. 3. With a few exceptions the chances of the patient returning to work after fracture in the neighbourhood of the ankle-joint is comparatively good. 4. Fractures involving the ankle-joint are seldom compound. If fractures in this region be compound it is evidence in favour of a direct violence fracture. 5. Disability following fractures in this region is due to bad alignment of the fragments, to synostosis of the bones, or to arthritis in the joint. 6. Patients over 50, and especially those over 60, have a more prolonged period of incapacity and much less chance of returning to work at all than younger patients. 7. The prognosis in cases of men drawing workmen's compensation and in injuries due to motor accidents seems to be less favourable than in fractures of other sorts, the date of the industrial labourer's return to work being often decided by his shop steward or his branch secretary and not by his medical adviser.

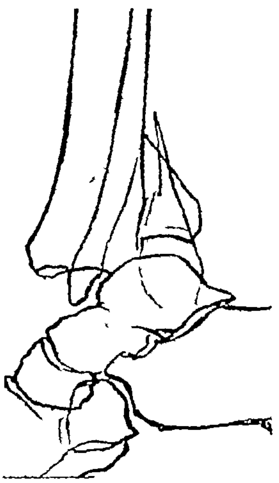
## VI.—MANIPULATIVE TREATMENT.

BY R. OLLERENSHAW, M.D.MANCH., F.R.C.S.ENG.,
ORTHOPÆDIC SURGEON, SALFORD ROYAL HOSPITAL, AND
ROYAL MANCHESTER CHILDREN'S HOSPITAL.

ON the practical aspect of this question I would like to say that I have no bias either in favour of open operation as opposed to more conservative means of treatment, or against it. I am strongly of opinion that operation should be reserved for those cases where satisfactory apposition and maintenance of that apposition cannot be achieved by manipulation and the usual splints or plaster.

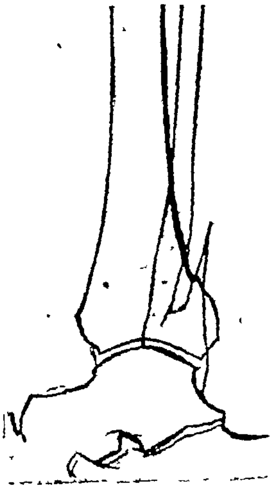
In the fracture clinic of my orthopædic department at Salford Royal Hospital I have had admitted to my wards during the past six months 43 cases of fracture of the long bones. There have been 11 operations only during that period. Five of these were cases sent to me "second-hand"—mal-union or non-union of fractures dating back three months to two years, so that only six primary open operations were done, and I find that with each succeeding year I do fewer primary open operations on fractures. The following are two cases of the worst type of ankle fracture which show completely satisfactory reduction by manipulation. The first (Fig. 20, A) was a very severe type of Pott's fracture and after reduction (Fig. 20, B) there is still a small gap between the edges of the fibular fracture. This is rather more than the gap in one of the cases just mentioned where operation was recommended. I do not think operation should be done here, and in this case of mine the end-result was perfect. Although I agree that a good reduction of the deformity is essential, it is not necessary to secure the most absolute precision in order to get complete return of function. Fig. 21, A shows the nearest approach to what I understand by a "Dupuytren fracture" seen in my department in seven years, and yet, although the displacement is so gross, the reduction (Fig. 21, B) shows good apposition, though not perfect, and the end-result was in every way excellent.

FIG. 20, A.



Ankle fracture with gross displacement.

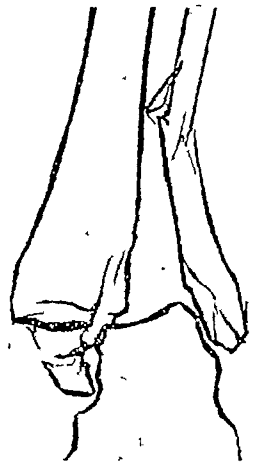
FIG. 20, B.



After manipulative reduction.

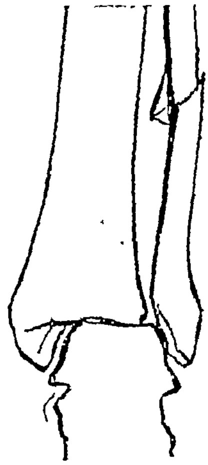
I believe that a very useful aid in difficult compound fractures above the ankle where the tibial diaphysis is projecting through the skin is to reduce the fracture and to maintain its position by plating the fibula.

FIG. 21, A.



Ankle fracture with gross displacement (Dupuytren type).

FIG. 21, B.



Same after manipulative reduction.

Through a small incision over the fibula a plate is fixed holding the fibula and controlling the lateral displacement perfectly. After healing of the wound has occurred and the fracture has become steady—four weeks later—the plate is removed under local anæsthesia. It has served its turn, and I believe that most plates used so close to the skin as this give trouble eventually.

# PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Stricture of the Œsophagus in Old People.*

THERE is one form of œsophageal stricture that has up till now escaped description in the text-books, but which cannot be rare, since Dr. Guisez, of Paris, has succeeded in collecting about 50 cases. This variety is always a result of improper mastication, whether this be due to bolting the food or lack of teeth. It is now proved that the œsophagus takes an active part in deglutition and that if it receives a badly prepared bolus of food it contracts vigorously. These spasms prevent the food passing down and this sets up inflammation of the œsophageal walls, œsophagitis, and consequent inflammatory stenosis. This innocent form of constriction is particularly interesting to recognise because it is usually mistaken for carcinoma of the œsophagus, which it resembles clinically. Œsophagoscopy alone can establish the correct diagnosis. The stenosis is really very serious and leads to complete dysphagia. Once the diagnosis is satisfactorily made, however, it is possible to begin treatment by local dilatation which will abolish the disability.

### *Pericardotomy.*

In a paper addressed to the Société de Chirurgie, Plisson and Rieux advocated more general resort to pericardotomy in cases of sero-fibrinous pericarditis. They presented a case in which grave signs of cardiac collapse required intervention. Operation was done under local anæsthesia, with the patient in a half-sitting position. The incision in the pericardium was flap-shaped. An extensive accumulation of serum and false membrane was evacuated from behind the heart. Marked tachycardia and arrhythmia soon became tranquil. The pericardium was left open, healing was uneventful, and the patient was discharged on the fifteenth day. In some cases secondary infection and prolonged fistula may occur, but this possibility does not contra-indicate the treatment described.

### *Pathogenesis of Adams-Stokes Syndrome.*

It is generally believed that the Adams-Stokes syndrome (slowing of the pulse with attacks of dyspnœa) indicates a lesion of the bundle of His, which forms a liaison between the auricle and ventricle. Dr. Géraudel, of Paris, however, has studied a case of Adams-Stokes disease and has made a series of 1200 thick sections, each of seven-thousandths of a millimetre, without finding any lesion whatever in the bundle of His. A complete investigation of the arterial supply of the heart has, on the other hand, led him to conclusions which support a theory which he had previously formed. From the results of other research he had, in fact, come to the opinion that the auricle and ventricle contract independently. Each chamber of the heart is controlled by a specific structure, which forms a kind of connexion or motor centre (plaque motrice) placed between the nervous system and the heart muscle. There is one motor centre for the auricle (the sino-auricular node or node of Keith and Flack) and one for the ventricle (the node of Tawara, bundle of His, or network of Purkinje). Each centre is supplied by an end artery. The activity of the centre, and in consequence the rhythm of the corresponding chamber of the heart, is a function of the quantity of blood passing through the artery; thus an increase in the supply produces a rapid beat and a decrease produces slowing. The slow ventricular rhythm of the Adams-Stokes syndrome is a result, then, of some obstruction at the level of the artery supplying the auriculo-ventricular node. Working on this original hypothesis, Dr. Géraudel looked for the obstruction and found it. Immediately above the point where the artery running to the auriculo-ventricular node branched off the artery to the septum showed a patch of endarteritis which considerably narrowed the lumen of the vessel. The discord of rhythm in Adams-Stokes syndrome is not, therefore, due to a dissociation between the auricle and ventricle along the connecting band which the bundle of His is supposed to form. The auricle is never directly associated with the ventricle. The difference in rhythms is a result of unequal blood-supply to the motor centres; when the blood-supply to the auriculo-ventricular node is reduced the rate of beat of the ventricle becomes slower.

### *Pyrenean Wool in Orthopædics.*

At the Faculté de Bordeaux Pyrenean wool has been in use for 25 years as a padding for splints and other orthopædic apparatus, serving thus instead of the usual jersey or tricot material. The Pyrenean material is not displaceable, forms no folds, and does not wrinkle. Both the local profession and visiting surgeons find it of great excellence.

### *Courses at the Hôpital Cochin.*

At the official opening of his clinical course at the Hôpital Cochin Prof. Widal, discussing bronchial dilatation, paid a most eloquent tribute to Laënnec, "the father of French clinicians," whose four cases, he said, practically covered the subject, save for the modern laboratory methods which now serve but to confirm his views. On Jan. 11th two complementary medical courses will begin at the medical clinic of this hospital. The first will deal with nitrogenous retention, urea of the blood and urine, determination of the Ambard constant, hypertensive states, retention of chlorides, diagnostic technique in diabetes, and thorough discussion of the examination of the cerebrospinal fluid. The second course will be devoted to hepatic affections and their diagnosis, duodenal tubage, digestive hæmoclasis, diagnostic technique in the several typhoid diseases, fixation, flocculation and skin reactions, cyto-diagnosis in pleural effusion, and the technique of basal metabolism. The lectures and demonstrations will be held at 2 P.M. daily and will continue until Feb. 3rd. A fee of 100 francs is asked for each course.

Prof. Marchoux, of the Pasteur Institute, well known for his contributions on fowl spirillosis, yellow fever, leprosy, malaria, and other subjects in tropical, colonial, and maritime medicine, was elected member of the Académie de Médecine on Dec. 22nd.

By presidential decree, Profs. de Lapersonne, Hutinel, Pierre Marie, Charles Richet, Letulle, Chauffard, and Weiss have been named honorary professors at the Faculté de Médecine.

The Paris municipal council has fixed new fees for hospital service in 1926. The daily fee for medical service will be 23 francs 32 centimes and for surgical and obstetrical service 24 francs 26 centimes. For hospitalisation of occupational accidents medical service will cost 30 francs 30 centimes, and surgical service 31 francs 53 centimes per day.

The Seine General Council has just taken up the question of securing a sufficient supply of convalescent serum for prophylactic use against measles. Thus far the supply of such serum has been limited to one or two hospitals where Debré and his associates have been active, and extension of the benefits obtained by using serum from convalescent cases of measles has been greatly desired for some time.

---

STAFFORDSHIRE GENERAL INFIRMARY: NEW OPERATING THEATRE.—A new operating theatre, which has been provided at a cost of about £5000, was recently opened by Sir John Bland-Sutton. In his opening address he reviewed the progress of surgery from pre-anæsthetic days, when strong assistants held the patient, to the present time, and remarked on the advantages which resulted from the harmonious working together of the hospital board of management and the surgeons. From this combination three things followed—namely, security for the patient, welfare for the community, and honour for the institution. The new building has been erected on the west side of the infirmary, with a northern light, and the accommodation includes a small theatre for septic cases, an anæsthetic room, and a preparation room. The equipment is of the most modern character. The Earl of Lichfield, president of the infirmary, presided, and members of the medical and surgical staff of the infirmary were present with their wives.

# The Services.

## PROMOTIONS OF MEDICAL OFFICERS.

The following list of half-yearly promotions was issued with the New Year Honours on Jan. 1st:—

*Royal Naval Medical Service.*—Surg. Comdr. R. W. B. Hall to be Surg. Capt., and Surg. Lt.-Comdr. A. E. W. Hird (Royal Naval Volunteer Reserve) to be Surg. Comdr.

*Royal Air Force.*—Squadron Leader F. C. Cowtan to be Wing Comdr., and Flight Lts. G. S. Ware, E. F. N. Currey, C. A. Meaden, and F. E. Wilson to be hon. Squadron Leaders.

## ROYAL ARMY MEDICAL CORPS.

Cols. L. F. Smith and H. O. B. Browne-Mason, late R.A.M.C., retire on retd. pay.

Lt.-Col. and Bt.-Col. W. R. Blackwell, from R.A.M.C., to be Col., vice Col. H. O. B. Browne-Mason.

Lt.-Col. G. G. Delap, from R.A.M.C., to be Col., vice Col. L. F. Smith.

The undermentioned Majs. to be Lt.-Cols.: D. Ahern, vice Lt.-Col. and Bt. Col. W. R. Blackwell, and B. H. V. Dunbar, vice Lt.-Col. G. G. Delap.

Capt. J. W. Hyatt is secd. for duty with the Sudan Def. Force.

Capt. J. Crean to be Temp. Capt. and temporarily relinquishes the rank of Capt.

Temp. Capt. G. L. K. Finlay relinquishes his commn. on account of ill-health and is granted the rank of Capt.

### RESERVE OF OFFICERS.

Lt. A. H. Levers, from Welch R., R.A.R. of O., to be Lt.

### MILITIA.

Capt. T. O. Graham to be Maj.

### TERRITORIAL ARMY.

R. Riley and G. B. W. Walker to be Lts.

## INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. J. L. Marjoribanks.

Capt. J. W. Van Reenan to be Maj.

Rochiram Udhamdas Hingorani, Janardan Madhav Gole, and Cheruvari Kottieth Lakshmanan to be Temp. Lts.

## DEATHS IN THE SERVICES.

Surgeon Rear-Admiral John C. Birkmyre Maclean, C.B. (retd.), who died on Christmas Day at his residence, 12, Penlee-gardens, Devonport, at the age of 76, was the son of the Rev. A. Maclean, D.D. Born in 1849, he received his education at Aberdeen University, where he graduated in medicine and surgery in 1871. He entered the Royal Navy as a surgeon in the following year and served for ten years as surgeon of the *Alexandra*. He was at the bombardment of Alexandria (specially promoted to staff-surgeon, Egyptian medal, with Alexandria clasp, and the Khedive's bronze star). He became fleet-surgeon in 1890, deputy inspector-general in 1898, and inspector-general of hospitals and fleets in 1903. For three years he was in charge of the Royal Hospital at Stonehouse, Plymouth, and retired in 1907. On the outbreak of the war, being then 63 years of age, he returned to duty and was appointed to the *Vivid* at Devonport, for the Naval Transport Service, and in January, 1917, he was gazetted a C.B. He was made a surgeon rear-admiral on the grant of military titles to the branch in 1918. He married, in 1802, Maude, eldest daughter of Mr. E. Hewlett, of the Priory, Totnes, who survives him with one son.

---

International Medical Cruise in the East.—Owing to the success of its last cruise the *Bruxelles Médical* has decided to charter a 12,000-ton steamer for another voyage at reduced rates for doctors and their families. The rates for medical men, it is announced, are: First class, $185; second class, $120; third class, at greatly reduced rates. The third class is intended for medical students who will be accommodated in six- to eight-berth cabins but will partake in the life on board of the first-class passengers (though not of their meals). The steamer will leave Marseilles on March 17th and will return on April 13th. She will visit Naples, Malta, Piræus, Constantinople, Smyrna, Rhodes, Cyprus, Beirout, Jaffa, and Alexandria. Easter Sunday may be spent in Jerusalem. Applications should be sent at once to Dr. Bernard, 62, Rue Froissard, Brussels.

## THE EXTRINSIC ORIGIN OF CANCER.

*To the Editor of* The Lancet.

Sir,—I should like to convey to Dr. William B. Coley my appreciation of the kind and generous way in which he has commented on our work in your issue of Dec. 26th last. In his words may be read the spirit of the real investigator—one who is ready to welcome the truth wheresoever and by whomsoever it may be found. Dr. Coley's own splendid record of endeavour in the treatment of malignant disease makes his words the more graceful. I gladly accept the opportunity offered by his letter of trying to clear away some misconceptions that appear to exist in regard to our work.

In two of the addresses[1] on the subject that I have delivered in the last two years I have endeavoured to present a simple yet complete summarised account of our views and of our investigations as they have progressed. On going through these papers I cannot find any omission of importance, or anything that should not be clear to those wishing to repeat our work. As a matter of fact, it would be possible to dispel all the misunderstandings that have arisen by direct quotations from the text of our published papers. Presumably, however, these have been read, though the details have not been completely grasped; consequently detached statements seem now to be required in order to make certain points clear.

First, Dr. Coley and I are not so far apart in certain views as he appears to think. He implies that I rule out bacteria in the ætiology of cancer; this is far from being the case. The essential principle in our working hypothesis is that many extrinsic causes—infective agents, chemical substances, X rays, and the rest—as well as intrinsic factors, such as senescence, *are all capable of producing a common condition of lowered vitality in the cell*, as the result of which malignant neoplasia may develop (vide infra). From this it will be clear that I have not for a moment myself "ignored or cast aside" the work of those who have attempted to assign to cancer a bacterial origin; I have merely stated that this is only one of many so-called "causes." I say "so-called causes" because, in my opinion, they are predisposing factors rather than actual causes in that these numerous agents can all produce a certain precancerous condition in the cell, which may or may not go on to cancerous development. It is possible that Dr. Coley has in his mind the further change from the common precancerous condition mentioned to malignant neoplasia as intrinsic; and, of course, it must be, and is. But this is a stage further than that produced by the predisposing factors, and there need be no reason for confusion. This explanation should dispose of the idea that I believe intrinsic factors alone are concerned in the onset of cancer.

Secondly, however plainly I have endeavoured to expound our working hypothesis, it does not appear to be generally understood. As stated in my last address, there can be no doubt that whatever the predisposing causes—the causes that lead to the common precancerous condition in the cell—the malignant neoplasia that may supervene is a *reversionary, and therefore specific, growth process* in whatever tissue it may arise. In these circumstances it has been essential to look back upon the beginning of growth in mammals—an interesting study in relation to cancer. Here was seen at once evidence of a normal malignant process—the invasive nutriment-seeking faculty of the trophoblast. This was considered alongside the following facts: first, as malignant neoplasia develops in any situation there is an increasing tendency of the cells to revert to the type seen in the earlier stages of development of the tissue concerned—a going back, as it were, to the trophoblastic type with all its powers of invasion and destruction; and, second, in chorion epithelioma alone is the malignant tissue an exact, and unvarying, reproduction of the tissue from which it has arisen—a tissue normally malignant and the most primitive in type. This retrogression on the part of somatic cells would be impossible if the cells were not free of differentiation-control; *consequently long before* reaching the trophoblastic phase they exhibit all the potentialities of it. I need not refer to the body of evidence in support of this view.

---

[1] The Lancet, 1924, i., 267; idem, 1925, ii., 1003.

So with the third misunderstanding, the last with which I propose here to deal, Dr. Coley compares lead with copper, and implies that the mode of action of the two in regard to cancer is similar, but more pronounced in the case of lead. It is not surprising, then, that many who do not read very carefully say, "Oh, yes, lead—another metal," as though we had simply tried and used lead because it is a metal. These critics also appear to think that there is a special virtue in heavy metals. Now I have repeatedly made it clear, or have tried to do so, that lead has been employed simply and solely because it has a definite effect on the chorionic epithelium *in particular*, and *on growth* generally—an effect which differs from that of the other metals tested, even though heavier than lead. The investigations, based on the working hypothesis described, had been in progress a considerable time before the use of lead was contemplated; and then only because the biological substance, probably fœtal, that normally checks the growth of the *chorionic* epithelium could *not* be isolated, as we still hope it may be. In other words, lead is only a substitute, and probably a poor one, for the biological inhibitor of the growth of the chorionic epithelium that eventually may be found. In spite of what Dr. Coley says, the fact that lead appears to have a similar effect on malignant cells supports rather than disproves my views as to the mechanism of malignant neoplasia, even without the backing, which exists, of a body of other evidence.

How willingly we all must echo the sentiments contained in the last paragraph of Dr. Coley's letter! Yet, at the same time, with so much evidence, not only scientific but also that of the history of cancer research, against the solution of the problem on the hypothesis of a specific cause, surely it is not unwise to open up another line of attack as we have done.

I am, Sir, yours faithfully,

Liverpool, Jan. 2nd, 1926. W. BLAIR BELL.

*To the Editor of* THE LANCET.

SIR,—With the argument of your distinguished correspondent, Dr. William B. Coley, of New York (Dec. 26th, p. 1358), many must agree. Even those who cannot concur in Prof. Blair Bell's views on the nature of cancer must acknowledge the significance and value of the curative results which he and his colleagues have obtained with colloidal lead. With Glover and Scott of America they share the credit of having opened out to us new and proved methods of treating cancer. Scott has recently[1] reported 11 cases of cancer where tumour masses have disappeared and ulcerated surfaces have healed under the exhibition of the serum of horses immunised against the pleomorphic microbe described independently by Glover and myself. These striking results constitute, in my opinion, the most significant contribution to the non-surgical treatment of cancer so far published. Scott had previously confirmed our view by isolating the Young-Glover microbe from all classes of cancer and with it producing malignant epithelial tumours in animals at the point of inoculation.[2] Loudon and McCormack,[3] of Toronto, have published similar confirmatory results and, within the past few days, in a personal letter I have received further confirmation from another American laboratory. In addition, Nuzum has recently produced a diffuse lymphomatous lesion in mice by the inoculation of the pleomorphic microbe which he obtains regularly from carcinoma, and has thus *confirmed my experimental findings* (1922) and added support to the view which I have urged that this "pseudo-leukæmic" lesion is in reality a diffuse malignancy. Maud Slye's experimental investigations, pursued from an entirely different angle, point to the same result. I have elsewhere shown how these findings throw a flood of light on the whole leukæmic process and have led to the discovery in the *leucocytes in human leukæmia* of a pleomorphic microbe similar to that previously found in the cancer cell.[4]

*This multiple confirmation* of the pleomorphism of the cancer parasite must lead speedily to a coördination of much effort which is at present scattered and apparently contradictory. Already its fruit is seen in a new and hopeful therapeutic measure. It is obvious that Nuzum's micrococcus is identical with the micrococcal variant of the cancer microbe which I described in 1921, and it follows, also, that the bacillus with which Blumenthal in Berlin (1924) has obtained positive experimental results, which have been confirmed elsewhere, and that the ultramicroscopic form which Blumenthal has found it necessary to predicate and which Gye and Barnard recently claim to have cultivated and photographed, are *all identical* with the corresponding forms of the microbe which I described in 1921. The sooner we face these issues squarely the sooner shall we be equipped for the tasks that lie ahead. A host of workers have shown that a pleomorphism similar to that of the cancer parasite is possessed by other micro-organisms which, like it, can each live an independent existence as coccus or bacillus, or filterable virus, &c. In the hands of Calmette and his co-workers the pleomorphism of the *B. tuberculosis* is leading to unexpected results; others have shown that the *Rickettsia prowazeki* and the *B. proteus* (X 19) of typhus are variables of one and the same microbe, and so on, and to those who are in touch with these big new developments it must seem likely that pleomorphism is behind the bacterial chaos of influenza, small-pox, measles, &c.

I am, Sir, yours faithfully,

Edinburgh, Dec. 31st, 1925. JAMES YOUNG.

## THYROID GLAND AND CALCIUM THERAPY.

*To the Editor of* THE LANCET.

SIR,—In text-books one finds thyroid gland very generally recommended for the treatment of chilblains. In my opinion any benefit derived is from the contained parathyroid, and in my *experience the administration* of thyroid often causes chilblains where they have not previously existed. At the present moment I have two patients, middle-aged women, under treatment by small doses of thyroid (gr. i. fresh gland daily) for slight though quite definite symptoms of myxœdema, which are relieved by taking this dose, but quickly recur on its intermission. They both tell me that since taking thyroid they have suffered considerably *from* chilblains, although before taking it they were immune to the trouble since the days of childhood. In both cases, while *admitting* other positive benefits, they blame the thyroid for the chilblains, and I think they are right. There is no other altered circumstance in their lives which might account for the chilblains. They have both taken thyroid fairly regularly for two years and have suffered from *chilblains this winter* and last. One of them took no thyroid September, 1924–February, 1925, and did not begin her chilblains till March, 1925. Both cases are relieved by taking calcium lactate.

Sir James Barr[1] holds that in chilblains the fixed *line in the circulation* is not diminished, so that there is no true œdema but the free calcium ions are diminished. Since thyroid secretion has the effect of increasing the calcium metabolism and the excretion of calcium, one would expect an excessive dose to produce symptoms of deficient calcium in the blood. My patients, however, are taking only just sufficient thyroid to keep the myxœdematous symptoms in check. The calcium content of the blood is said[2] to be diminished in both hyper- and hypo-thyroid states, but I have not known a case of Graves's disease with chilblains. I imagine this is due to the good peripheral circulation and the fact that the parathyroids are also over-functioning. I have also a case of pituitary tumour, taking thyroid gland, gr. v.–x., daily in the hopes of influencing the growth of the tumour. She does not suffer from chilblains or show other signs of calcium deficiency (metrorrhagia, &c.), but in her case the parathyroids are in all probability fully functional.

[3] Can. Lancet and Practitioner, November, 1925.

[4] Edin. Med. Jour., 1922.

[1] Barr: Brit. Med. Jour., Sept. 24th, 1910.

As cases of myxœdema (not those following thyroid extirpation where the parathyroids are left) are probably suffering from atrophy of both thyroid and parathyroid, and since the modern preparations of thyroid gland contain little or no parathyroid, it seems rational that these patients should be treated with preparations of both glands. Probably any good results in the past obtained from giving thyroid in chilblains were due to the contained parathyroid, which, I understand from the makers, is now very generally extracted. I am, Sir, yours faithfully,

Walmer, Dec. 30th, 1925. D. C. NASMYTH.

## PSYCHO-ANALYSIS AND SUICIDE.

*To the Editor of* THE LANCET.

SIR,—One hears occasionally of suicide being ascribed to psycho-analysis, but a recent case appears to be the first in which the assertion can be examined. In the *Times* of Dec. 29th is the report of an inquest at which a medical witness said the patient had been taken to a psycho-analyst, "but the treatment proved too great a strain and the damage was intensified and produced a morbid condition of introspection and, through laying bare his subconscious mind, injured his mind very greatly, and he had to give up the treatment." Also, "the cause of the condition to which he arrived was the psycho-analysis." There were references to analysis as a "dangerous weapon."

I am a physician and use whatever means I consider suitable to the individual case. This gentleman came to me, with his father, on Nov. 16th. My notes of the interview record his physical condition and a few symptoms. I told his father that I did not consider analysis was desirable, but suggested that he should come to me for a few talks concerning his troubles. He came again on Dec. 7th. My notes show that nothing of importance cropped up. On the 9th he talked spontaneously of fairly recent events to which he gave an exaggerated emotional value that I sought to minimise. On the 10th he said that his father was not in favour of further treatment. We discussed how he ought to look at his troubles and handle them in the light of his own temperament, and he parted from me with no indication that the talks had been regarded as other than helpful.

In an analysis many days are spent in going over the patient's ordinary life before analysis proper can begin. The brevity of the treatment in this case is sufficient indication that no analysis was done, and, as I have shown above, none was attempted. These facts speak for themselves, and, apart from them, I will ask your readers to judge the conduct of the medical witness by the ordinary standards of professional conduct as applied to any specialty where psychological questions do not arise.

I am, Sir, yours faithfully,

MILLAIS CULPIN.

Queen Anne-street, W., Jan. 1st, 1926.

*** Comment on Dr. Culpin's letter will be found on p. 79 under the heading of Medicine and the Law. —ED. L.

## GLYCOSURIA AND LIFE ASSURANCE.

*To the Editor of* THE LANCET.

SIR,—Will you, in justice to the assurance company and myself, allow me a brief reply to their statement and your comment thereon? The account given me by the proposer of the method of testing the urine is evidently not correct, but he would not necessarily know that a portion of the specimen had been reserved for further examination. The presence of glycosuria was, however, never in doubt and is admitted. My point was that this was used as a ground for rejection at that time, without examination of the blood, and that when the assurance company were informed of the result of the analysis they refused to modify their attitude. I now have the letters of the company to the proposer before me, and there can be no doubt on that point. My main contention, therefore, remains unchallenged, which is that with so small a quantity of sugar in the urine no estimate should be formed of the significance of glycosuria without examination of the blood.

I am, Sir, yours faithfully,

A. KNYVETT GORDON.

Bedford-square, W.C., Jan. 1st, 1926.

## PROFESSIONAL CRITICISM OF THE GENERAL MEDICAL COUNCIL.

*To the Editor of* THE LANCET.

SIR,—Dr. Layton gives your readers to suppose that, when writing in your issue of Dec. 26th last (p. 1359) on the General Medical Council and professional standards, I "openly state" that I am in the habit of signing false statements. I regret that my letter could have been so misread. May I say that I am not in the habit of signing such statements, although I pointed out the difficulty in which the practitioner is placed, and expressed a hope that the Council should distinguish between technical inaccuracy and fraud or carelessness.

I am, Sir, yours faithfully,

Sevenoaks, Kent, Jan. 3rd, 1926. GORDON WARD.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 26TH, 1925.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 178 (last week 180); scarlet fever, 1516; diphtheria, 847; enteric fever, 21; pneumonia, 1329 (last week 1832); puerperal fever, 34; cerebro-spinal fever, 5; acute poliomyelitis, 7; encephalitis lethargica, 34; dysentery, 7; ophthalmia neonatorum, 86. The holiday season no doubt explains the fact that with the single exception of dysentery the number of cases reported is smaller for every notifiable disease this week than it was in the previous week. There were no cases of cholera, plague, or typhus notified during the week.

Of the 178 cases of small-pox, 106 were reported from the county of Durham, 30 from the county of Derby, and 14 from the county of Nottingham.

*Deaths.*—In the aggregate of great towns, including London, there was only 1 death from enteric fever, none from small-pox, 72 from measles, 11 from scarlet fever, 30 from whooping-cough, 36 from diphtheria, and 85 (last week 132) from influenza. In London itself there were 37 deaths from measles, 10 from diphtheria, 21 from diarrhœa and enteritis under two years, and 14 from influenza.

BRITISH CHARITIES ASSOCIATION.—The second annual report, to July, 1925, states that grants have been made to every approved voluntary hospital which applied, and also to those hospitals which coöperated with the British Charities Association during the year. A sum of £19,848 was distributed to hospitals in London, £15,000 of which was handed to King Edward's Hospital Fund, and £10,000 to hospitals and charities outside the London area. At Christmas a supplementary distribution of £20,000 was made to King Edward's Hospital Fund for the London hospitals, and £45,000 to the various hospitals outside the London area, bringing the total since midsummer, 1924, to over £95,000. During the two and a half years since its foundation the British Charities Association has distributed a net total of £121,000.

---

# Obituary.

## LOUISA BRANDRETH ALDRICH-BLAKE, D.B.E, M.D, M.S LOND

WE have already briefly announced the death on Dec. 28th last of Dame Louisa Aldrich-Blake, whose memory will live as a great leader, a wise administrator, and a brilliant surgeon

Louisa Brandreth Aldrich Blake was born at Chingford Rectory on August 5th, 1865, the daughter of the Rev Frederic James Aldrich Blake, sometime rector of Welsh Bicknor, her forbears including a number of Aldrichs holding distinguished positions in the navy She was by birth and character of the stuff of the great leaders of English conservative tradition A landowner herself, she came to understand the duties of administration, sharing the responsibilities of her tenants and loving the soil of her native county It is recorded of her that she had a natural gift for healing, and that at the age of 8 she and her sisters organised an animal hospital to which the villagers brought their sick and wounded pets and that at 10 years she had performed her first operation on one of them No doctor was immediately available in the village, and when she was not much older she undertook more serious duties and set a broken leg before the patient was taken away to hospital Louisa Aldrich-Blake was sent first to a private school at Malvern and afterwards to the Ladies College at Cheltenham, from which she took the preliminary scientific examination of London University Entering the London (R.F.H ) School of Medicine for Women in October, 1887, she graduated in medicine five years later with first-class honours in medicine and obstetrics, again taking first-class honours and qualifying for the gold medal in the B.S. examination of the following year In the two succeeding years she went on to take the higher diplomas in medicine and surgery offered by London University, being the first woman to obtain the M.S degree It was in this year that she was appointed assistant surgeon to the New Hospital for Women (later renamed the Elizabeth Garrett Anderson Hospital), becoming full surgeon in 1902 and senior surgeon in 1910 At the Royal Free Hospital she was the first woman to hold the post [illegible] registrar, and was for several years anæsthetist and lecturer on anæsthetics Soon after the outbreak of war in 1914 she was invited to become consulting surgeon with charge of beds at this hospital At about the same time she organised a group of medical women who were prepared to establish a hospital at Brussels, but, being prevented from so doing organised a unit near Cherbourg at which many Belgian and French sick and wounded were treated. In the autumn of the following year she served under the Anglo-French Red Cross at Royaumont, assisting Miss Frances Ivens and relieving her of a large part of the many operations performed there During 1916 her work at the Royal Free Hospital included charge of surgical out-patients on two afternoons a week, and gradually her mornings were devoted to work in the theatre and surgical wards, where she replaced members of the staff who had gone on foreign service During this period she acted as visiting surgeon to the W.A.A C Hospital at Isleworth

DAME LOUISA ALDRICH BLAKE.

For 20 years Miss Aldrich-Blake had been intimately associated with the administration of the London School of Medicine for Women She was appointed vice-dean to Miss J Cock in February, 1906, and succeeded her as dean in February, 1914 Dr May Thorne who, as honorary secretary of the school, worked with her for 17 years, speaks of her as a wise administrator whose mind was orderly and whose life was arranged for the proper discharge of manifold duties. "Dame Louisa," Miss Thorne writes, "gave everyone the impression that she had ample leisure, for she never hurried, and this in spite of the fact that for many years she worked every night well into the morning hours She had an extraordinary power of undertaking and performing an enormous amount of good work which was of far-reaching usefulness not only for the school, the Elizabeth Garrett Anderson Hospital, the Royal Free Hospital, the Canning Town Settlement, and many medical societies, but also for numerous individual students and medical women. She loved what was good and true The things that made her justly angry were carelessness, leakage of work done at committees, and tale-bearing She often took time to master some problem that arose in the course of her work as dean, but, once grasped, she never forgot any detail of it, even after a lapse of years. No doubt a larger gift of revealing the sympathy that was in her would have made her more widely understood, but to the hundreds of students who passed through the school her unfailing readiness to bear their burdens, her calm mind, self forgetfulness, and steadfastness, will remain an inspiration."

Miss Aldrich Blake was a surgeon of excellent judgment. "From the outset of her medical career," writes Miss Elizabeth Bolton, "she realised the need of long and thorough training for operative work, and how much more was involved in the making of a surgeon than mere manipulative skill. She grasped the supreme importance of anatomy and physiology as a groundwork for surgical work, she had unusual mechanical knowledge and joy in the right use of instruments, her technique was sound, and she ever remembered the sensitiveness of living tissue. To any difficult problem she would give much thought, and, what is perhaps more rare, thought after as well as before action. Her judgment was direct and clear and she had developed unusual keenness of diagnosis

"Miss Aldrich-Blake was one of the first in this country to undertake Wertheim's operation for carcinoma of the cervix, and in 1903 she brought forward the advantages of abdomino-peritoneal resection of the rectum. She got through an enormous amount of work in later years, but, with it all, she never failed to find time to help at once any of her junior colleagues who needed her To her nothing was trivial The small operation as well as the big was intensely interesting and had its claims, and she paid them in full. The personal side of the patient under her care interested her, and she impressed on those under her the insult of daring to deal with patients with [illegible] half one's attention She was, in fact, a great craftsman in the work she specially made her own, and to the end she was a student."

But while herself so sure and good a surgeon, she was determined that others should be so too. "It was characteristic of her," writes Miss L. Martindale, "that no one ever applied to her for help in vain. Women in the past had few opportunities for posts as assistant surgeons. Dame Louisa Aldrich-Blake helped many of them in their early days, and there are many women surgeons now holding important positions and doing brilliant surgery who owe their successful careers to her. A telephone call and a conversation always brought her to their aid. Many is the time she has assisted young surgeons in their first operations on private patients, travelling often at night without thought of personal recognition."

No account of Miss Aldrich-Blake would be complete without some mention of the qualities of heart and mind which made her so much more than a wise administrator and a skilful surgeon. She was first and foremost sincere, upright, and of unswerving principle in the face of difficult problems, confident in herself and yet unusually silent and reticent as to her achievements. She once said she wished human life were longer; there were so many things she would like to do. Her fine brain, judgment, and devotion to work would have ensured success in any field. Lord Riddell, chairman of the Royal Free Hospital, has said truly that had she not been an eminent surgeon she might well have made a distinguished judge, for she had the habit of mind of dealing with every subject on its merits irrespective of her personal interests. Apart from her medical work she was fond of travel, and was interested in every kind of sport. Although not a great reader, she had a freshness in her judgment of political situations which was stimulating to others. Children she loved and instinctively they loved and trusted her. Family relationships meant much to her; that of aunt and nephew, she once said, was one of the most satisfactory in the world.

It was at the jubilee last year of the London School of Medicine for Women that Miss Aldrich-Blake's work was recognised by her appointment as a Dame of the Order of the British Empire, and there has never been an honour granted which was felt to be more appropriate or has been given wider approval.

## RICHARD CATON, C.B.E., LL.D., M.D. EDIN., F.R.C.P. LOND.

AFTER a long and distinguished career in Liverpool, Dr. Richard Caton died at Haslemere, Surrey, on Jan. 2nd.

Richard Caton was born at Bradford, and was educated at Scarborough Grammar School and Edinburgh University, where he qualified as M.B., C.M. in 1867. Three years later he gained the gold medal for his M.D. thesis on the migration of leucocytes, and in 1888 was elected F.R.C.P. Lond., becoming a member of the Council, and Harveian lecturer to the College in 1904. It was in the year following qualification that he settled at Liverpool, where from the first he was prominently associated with religious and civic activities. His professional reputation grew rapidly. At first he worked at the old medical school attached to University College; later he was foremost in the movement which ultimately secured university status for Liverpool. To the end his interest in the University was living and effective. At one time professor of physiology, he succeeded to the office of pro-Chancellor, and in this capacity represented Liverpool at the seventh centenary of the University of Padua. Nor were his civic attainments negligible. As a scientist he was greatly interested in physiology in its relation to the health of the people, and his knowledge of public health made him a most useful member of the City Council and especially of those committees which dealt with secondary education and the housing of the poor. Of these committees he was chairman. His commanding position was recognised when, in 1906, he was elected Lord Mayor. Dr. Caton was physician to several Liverpool hospitals, including the David Lewis Northern Hospital and the Royal Infirmary. He was president of the Medical Institution in 1896-97, and was vice-president of the Liverpool School of Tropical Medicine. Interested in various medical subjects, and especially in early endocarditis, for which he recommended blistering ("Caton's blisters"), he was at the same time a keen classical archæologist, and will be remembered for his writings on Hippocrates, Asklepios, and the Medicine God of the Egyptians. His learning was recognised by three universities, Edinburgh, Padua, and Liverpool, which conferred on him the degree of LL.D., and he was created a C.B.E. in recognition of his work as chairman of the West Lancashire Nursing Service Committee.

"Dr. Caton," writes a correspondent, "never spoke without one feeling the vivid and forceful personality behind his words. He was a revered and commanding figure in every circle where he was known, and Liverpool, no less than Liverpool's medical profession, mourns his loss as that of one of her great men."

Dr. Caton married the daughter of Mr. William Ivory, of St. Roque, Edinburgh, and had two daughters, one of whom is married to Prof. H. A. Ormerod, of the University of Leeds.

## AGNES ELIZABETH HENDERSON, M.B.E., M.D. BRUX., L.R.C.P. EDIN.

Dr. Agnes Henderson, whose death occurred in a London nursing home on Dec. 29th last, was one of the senior missionaries of the United Free Church of Scotland. Daughter of the late Sir William Henderson, LL.D., who was Lord Provost of Aberdeen from 1886 to 1889, and grand-daughter of Mr. George Thompson, M.P., she studied at the London School of Medicine for Women, taking the triple Scottish diploma in 1889 and the Brussels M.D. for practitioners in the following year. She went out to India in 1890, and for 32 years worked unremittingly among the women in the Central Provinces, where she was in charge of the hospital at Nagpur. Even though she went on the retired list in 1922, she continued to live in Nagpur, and busied herself with the responsibility of raising funds from among her Indian friends for a new hospital building. The municipality also came generously to her assistance. During the war years Miss Henderson spent some time in this country as a medical officer among women and girls in munition factories. In 1923 she was made a Member of the Order of the British Empire. She returned to England early last summer and was living quietly in Buckinghamshire.

## JAMES MURIE, M.D. GLASG., LL.D. ST. AND.

AT the age of 93 Dr. James Murie died at Rochford, Essex, on Dec. 21st, having outlived all his relatives.

James Murie was born at Glasgow and studied natural history and medicine at the University, where he took his M.D. degree in 1857. The buildings of the University now stand on land which his father used to farm. Dr. Murie started his adventurous career by going to West Africa to report on mercantile products. Upon his return he became pathologist at the Glasgow Royal Infirmary, and after a few years of desultory teaching, during which he was looking out for another opportunity to go to Africa, made the acquaintance of David Livingstone, J. H. Speke, and other famous travellers, and was appointed medical officer and naturalist to an expedition led by John Petherick, which was to convey stores to Gondokoro, to meet Speke and Grant, who were investigating the source of the Nile. Dr. Murie succeeded on this expedition in making important collections of animals and plants; the fauna and flora of the Sudan was at that time little known. On coming back to England it was his wish to accompany Livingstone on his Zambesi venture, but the appointment went to Dr. (afterwards Sir) John Kirk. In 1865 Murie was made prosector to the Zoological Society, in which occupation he remained for six years. In 1868 he had been elected a Fellow of the Linnean Society of London, and in 1876 he became assistant secretary. He resumed his medical work, and was at one time lecturer on comparative anatomy at Middlesex Hospital and physician to the Bethnal Green Asylum. In 1877 he received the degree of LL.D. from the University of St. Andrews. After succeeding to the post of librarian of the Linnean Society, which he held for eight years, he retired in 1888 to Leigh-on-Sea. Since that time he has led a very solitary life, devoting himself to the study of the fish and fisheries of the Thames estuary. He enjoyed a pension from the Linnean Society, but in his later years was able to publish comparatively little work.

## REGINALD WOOLSEY STOCKS, M.R.C.S. ENG., D.P.H. BIRM.

DEEP regret is felt in public health circles at the untimely death of Dr. Woolsey Stocks, medical officer of health and school medical officer for West Bromwich. He had already made his name as a keen and progressive member of the service, with a special interest in the welfare of mothers and children. As recently as Dec. 12th we commented on his report in which he urged the need for systematic antenatal examination and pleaded for the expenditure of greater care on the well-being of small children.

Born in London in 1882, Dr. Stocks was educated at Dulwich College, at the Universities of London and Birmingham, and at St. Thomas's Hospital. After house appointments at the Queen's Hospital, Birmingham, he became resident medical officer at the Children's Hospital, Birmingham, in 1909. After this he held public health appointments in Wandsworth, and in 1911 was appointed to West Bromwich. For several years Dr. Stocks was one of the hon. secretaries of the National Baby Week Council, and his advice was invaluable to this voluntary body in its many activities. He also took a very active interest in the work of the maternity and child welfare group of the Society of Medical Officers of Health and was its secretary from its institution till the current year, when he was unanimously appointed president, being also the representative of the group on the council of the parent society. Dr. Stocks was gifted with a charming manner, and was able to put forward his views with energy and decision, without leaving the sting of resentment amongst those who differed from him. He was deservedly popular and the public health service is the poorer for the loss of a man with his high ideals.

## DAVID CHARLES LLOYD OWEN, M.D. BIRM., F.R.C.S. IREL.

IN his eighty-second year, Dr. Lloyd Owen, formerly of Birmingham, died at Harlech on Christmas Day. He was descended from an ancient Welsh family deriving its origin from Scissyllt, Lord of Ardudwy, in Merionethshire, and was educated at the University of Birmingham and Paris. Qualifying as M.R.C.S. in 1865, he settled in Birmingham, where he specialised as an ophthalmic surgeon, and where, until his retirement a few years ago, he was surgeon to the Birmingham and Midland Eye Hospital and consulting ophthalmic surgeon to the Hospital for Sick Children and the General Hospital. Dr. Owen took considerable interest in public affairs, and became J.P. for the county of Warwick and a Knight of Grace of the Order of St. John of Jerusalem. He was also president of the Midland Medical Society, and of the Ophthalmological Section of the British Medical Association in 1890. These offices represent only a few of his activities, both medical and social, and his contributions to the literature of ophthalmology were considerable. He translated Giraud-Teulon's book on the eye, published "Elements of Ophthalmic Therapeutics" in 1890, and produced numerous lectures and papers, including the Middlemore lecture, on Pain in Eye Disease, of 1896.

## JOHN PREST WIGHTMAN, M.R.C.S. ENG.

Dr. J. P. Wightman, who died on Dec. 19th at Newby, Scarborough, after a week's illness, was elder son of the late Charles John Wightman, of Rawdon, Yorks. He was educated at St. Bartholomew's, qualifying in 1891, and after holding resident posts at the Hospital for Children, Myrtle-street, Liverpool, and the Sanatorium for Consumption, Bournemouth, he settled in York, where he built up a large practice in the Mount district, and was appointed honorary medical officer at the York Dispensary. He was an active member of the York Medical Society and the Leeds and West Riding Medico-Chirurgical Society, and made several contributions to medical journals on clinical subjects in which he was specially interested, such as empyema in childhood and hæmophilia. Six years ago Dr. Wightman left York and settled in Scalby, entering into partnership with Dr. B. G. Forman. He leaves a widow and one son, who is a medical student at Cambridge.

# Medical News.

UNIVERSITY OF OXFORD.—The following degrees have recently been conferred:—

*Doctor of Medicine.*—H. M. MacKeith.

*Bachelors of Medicine.*—C. W. Simpson, L. J. Barford, F. J. Bach, N. Chilton, S. Howard, and V. H. Brink.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the subjects indicated:—

*Surgery.*—S. Douglas, Univ. Coll. Hosp.; E. W. Hayward, Cambridge and London Hosp.; E. Kessel, Westminster Hosp.; B. A. Perritt, Petrograd; I. Rivlin, Middlesex Hosp.; P. H. Row, London Hosp.; F. Smith (Sect. II.), Manchester; and J. A. H. Sykes, Edinburgh and Middlesex Hosp.

*Medicine.*—R. F. Ashkenny, Cambridge and London Hosp.; A. K. A. Carter, Univ. Coll. Hosp.; C. E. Hagenbach, St. George's Hosp.; R. D. Mason, St. Mary's Hosp.; M. Schwartzman, Odessa and Middlesex Hosp.; and F. Smith (Sect. II.), Manchester.

*Forensic Medicine.*—R. F. Ashkenny, Cambridge and London Hosp.; C. E. Hagenbach, St. George's Hosp.; B. D. Jain, Charing Cross Hosp.; S. A. Jocelson, London Hosp.; E. H. Rampling, St. Thomas's Hosp.; C. H. Spencer, Manchester; and J. M. F. Whitby, St. Thomas's Hosp.

*Midwifery.*—A. M. El Mishad, Guy's Hosp.; R. C. Glover, Leeds and St. Bart.'s Hosp.; T. A. Lazaro, St. Bart.'s Hosp.; and J. Shibko, Cardiff.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: R. F. Ashkenny, S. Douglas, C. E. Hagenbach, T. A. Lazaro, M. Schwartzman, and F. Smith.

ROYAL SOCIETY OF ARTS.—A lecture by Prof. J. McLean Thompson on Some General Problems of the Transport by Sea and Conservation in Store of Ripe Fruit will be given at the Society's house in John-street, Adelphi, London, W.C., on Wednesday, Jan. 27th, at 8 P.M. On Feb. 10th Prof. J. C. Drummond will lecture on Modern Views of Vitamins, and on Feb. 24th Mrs. Mary Fishenden, of the Fuel Research Board, will give an address on Domestic Heating.

MEDICAL SOCIETY OF LONDON.—The programme for the second half of 1925–26 session is as follows: On Jan. 11th, at 8 P.M., a pathological evening will be held. On the 25th, at 8.30 P.M., a discussion on Manipulative Treatment in Medicine and Surgery will be introduced by Mr. R. C. Elmslie and Mr. W. R. Bristow. On Feb. 8th, at 8.30 P.M., a discussion on Right Iliac Fossa Pain will be introduced by Mr. H. W. Carson, Dr. A. F. Hurst, and Dr. T. W. Eden. On the 22nd, at 8.30 P.M., a discussion on the Ætiology and Diagnosis of Gall-stones will be introduced by Sir Humphry Rolleston, Mr. R. P. Rowlands, and Dr. Robert Knox. On March 8th, at 8.30 P.M., a discussion on Obscure Pyrexia in Adults will be introduced by Sir Thomas Horder, followed by Dr. C. R. Lakin and others. On the 22nd, at 8.30 P.M., a paper on the Use of Lead in the Treatment of Malignant Disease will be read by Prof. Blair Bell, followed by Dr. J. G. Adami, Sir Lenthal Cheatle, and others. On May 10th, at 8 P.M., a general meeting will be held, followed at 9 P.M. by the annual oration to be delivered by Sir Berkeley Moynihan. The Lettsomian Lectures on the Principles of Treatment in Relation to Diseases of the Nervous System will be delivered at 9 P.M. on Feb. 15th, 24th, and March 15th, by Dr. E. Farquhar Buzzard.

The death is announced of Dr. J. Bryce McMurrich, surgeon on board the Canadian Pacific liner *Melita*. Dr. McMurrich, who was a graduate of Trinity Medical College, Toronto, and was about 50 years of age, died suddenly at Jarrow railway station.

Welfare Centre at Llandudno.—On a site given by Lord Mostyn a maternity and welfare centre, with accommodation for clinic and welfare work, an operating room, and offices, will be erected. On the upper floor there will be five maternity wards. The centre will form part of the local war memorial.

Dublin (83) General Hospital.—The annual dinner of the Dublin unit of the Dublin (83) General Hospital was held on Jan. 2nd in the Royal College of Surgeons, Dublin. Colonel Sir William Taylor, organiser of the hospital, presided, and of the whole unit of 28, 18 were present. Of the remainder four have died, the most recent death being that of Major A. J. Blayney last July.

The King has sanctioned promotions and appointments to the Order of the Hospital of St. John of Jerusalem in England amongst the following members of the medical profession: Colonel Sir George Hastings, V.D., and Surgeon-Captain Montague Henry Knapp, R.N., as Knights of Grace; and Lieut.-Colonel Robert Frazer Standage, C.I.E., I.M.S., Captain Hugh Falkenberg Powell, M.B.E., Dr. George Pugin Meldon, Mr. Seton Sidney Pringle, O.B.E., F.R.C.S.I., Dr. Eustace George Carter, O.B.E., Colonel Francis Darlow, R.A.M.C., T.A., and Dr. Russell Facey Wilkinson, M.V.O., as Esquires.

Royal Patronage for Hospitals.—The Queen has consented to become patron of the Elizabeth Garrett Anderson Hospital in place of the late Queen Alexandra. The Duchess of York has consented to become patroness of the British Home and Hospital for Incurables, Streatham, in place of the late Queen Alexandra. Princess Mary Countess Lascelles has accepted the presidency of the Yorkshire Federation for Maternity and Child Welfare in succession to Lady Irwin, wife of the Viceroy-designate of India. Her Royal Highness will fulfil her engagement to open the new Whitehaven and West Cumberland Infirmary at Whitehaven Castle on Jan. 22nd.

Bad Sanitary Conditions in Elementary Schools.—The medical officer to the Billericay Rural District Council has reported on the conditions found in the church and council schools at Wickford. At the council school, which has 160 children on the roll and has accommodation for 170, one room used as a classroom has no cross ventilation and no fireplace, and the heating by means of a radiator is entirely insufficient. There were only two drinking mugs provided and two clean towels were allowed per week for the whole school. At the church school there was a class of 50 children in a room suitable for 30. The heating was inadequate and the walls were damp. The medical officer's reports have been forwarded to the Essex Education Committee.

Fellowship of Medicine and Post-Graduate Medical Association.—The Prince of Wales's General Hospital, Tottenham, N., is holding an intensive course from Jan. 11th to 23rd. It will include daily morning demonstrations of clinical methods, lecture-demonstrations of groups of selected cases in the afternoons, and work in the general and special departments of the hospital. A special feature of the course will be the afternoon lectures at 4.30, free to general practitioners who are members of the N.E. London Post-Graduate College and to members of the Fellowship of Medicine. The opening lecture will be given by Dr. Eric Pritchard on the Principles of Nutrition. Two special Saturday morning demonstrations will be held at the N.E. Fever Hospital and the L.C.C. Mental Hospital. A series of demonstrations in the diagnosis and treatment of the acute infectious diseases will be given by Dr. Frederic Thomson at the N.E. Fever Hospital on Wednesdays at 2.30 P.M. and Saturdays at 11 A.M. from Jan. 13th to 30th. From Jan. 18th to 30th the Queen's Hospital has arranged a special course on diseases of children. Morning and afternoon sessions will be held daily, and the programme consists of lectures and clinical demonstrations on medical and surgical diseases of children, including all the special departments. From Jan. 18th to 29th there will be an all-day course in cardiology at the National Hospital for Diseases of the Heart. The opening lecture of the Fellowship's new series will be delivered by Dr. Herbert Spencer on Abdominal Palpation in Pregnancy (with lantern demonstration). These lectures are free to members of the medical profession. A copy of each syllabus of the foregoing courses and of the programme of the General Course arranged by the Fellowship may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Beckett Hospital, Barnsley.—This hospital, which was enlarged in 1912, is to be further extended by the addition of a new ward for women and children. Towards the £22,000 which the work will cost, the local Miners Welfare Committee have granted £12,000, on condition that extra provision is made for casualties and out-patients.

North Staffordshire Medical Society.—A clinical meeting will be held at North Staffordshire Royal Infirmary, Stoke-on-Trent, on Jan. 14th, at 3.30 P.M. Practitioners will be admitted on presentation of card. The president for this year is Mr. E. E. Young, and the joint hon. secretaries Dr. A. W. Gill and Dr. E. C. Myott.

The Sheffield Hospitals.—The report of the Sheffield Joint Hospitals Council for 1924 has at last been issued. During the year there were 428,000 attendances of out-patients at the Sheffield hospitals, which spent nearly £1000 a month on milk and coal alone. The "Penny-in-the-Pound" fund produced over £94,000, but the balance owing to the bankers at the end of the year exceeded £91,000.

Bradford: New Infirmary.—The board of management is about to proceed with the erection of a new infirmary which, in addition to the ordinary medical and surgical wards, will have special departments for X ray, electro-therapy, and artificial sunlight. The total cost is estimated at £500,000, and three-fifths of the amount has yet to be raised.

Unused Health and Unemployment Insurance stamps of the denominations which were in use up to Jan. 4th, 1926, if they have not been affixed to any material, will be accepted at any Post Office in exchange for Health and Pensions Insurance stamps and Unemployment Insurance stamps of the new values. National Health Insurance stamps will not be accepted in exchange for Unemployment Insurance stamps. These arrangements will remain in force up to Jan. 31st.

National Memorial to Queen Alexandra.—The King and Queen have approved the suggestion that the national memorial to Queen Alexandra should take the form of a fund to develop the work of Queen Victoria's Jubilee Institute for Nurses. It is proposed to devote one half of the fund to strengthening and developing the work of the 600 local nursing associations, and a further portion will be allocated to the Nurses' Long Service Fund to provide pensions for Queens' nurses who have served for 21 years.

Psychologists and East African Tribe.—Dr. C. J. Jung, of Zurich, and Dr. H. Godwin Baynes, of London, have arrived in East Africa with the intention of spending six months amongst the Bagishu on Mount Elgon. These people are a mixture of the Bantu and Nilotic races and possess an extensive mythology. By investigating their customs and beliefs Dr. Jung and Dr. Baynes hope to throw light on the subject of the existence of the primitive in all men, whether civilised or not. Unfortunately the work will have to be done through interpreters.

Biddulph Orthopædic Hospital.—The trustees of this North Staffordshire hospital have accepted an offer from the Lancashire County Council to purchase the hospital and estate. The hospital, which was given by Mr. Robert Heath on condition that it should always be used for orthopædic work, was opened by the Prince of Wales in June, 1924, but in less than 12 months it had to be closed owing to lack of public support and the heavy cost of equipment, adaptation, and maintenance. Staffordshire now has no means of dealing with the majority of the waiting orthopædic cases, which are said to be very numerous.

Small-pox in Durham and Rawmarsh.—During the last quarter 630 cases were notified in Durham county in the administrative country area, and 15 in the county boroughs. In the administrative county of Durham during the four weeks of December the number of cases has been 80, 83, 110, and 90 respectively. In some districts in Durham county only about 30 per cent. of the children are vaccinated. Every hospital in the affected area is full. Durham County Health Committee has been obliged to send 50 cases of tuberculosis home in order to free hospitals at Birtley and Sealburn for small-pox, and both hospitals are now full. Ninety cases of small-pox are under treatment at Rawmarsh, near Rotherham, and 5 at Rotherham. The Sunday and day schools at Rotherham will remain closed for some time. Some patients have been sent to Sheffield for treatment, owing to want of accommodation. Derby small-pox hospital is full of patients, and the medical officer has issued a warning to the public of the danger of the disease spreading. The chairman of the health committee reports that the disease has reached epidemic proportions, and has cost the town thousands of pounds in the past year; 40 patients were taken to hospital in Christmas week.

GRESHAM LECTURES.—Sir Robert Armstrong-Jones is to deliver lectures in Physic at the Gresham College, Basinghall-street, London, on Jan. 20th and the two following days. The lectures founded by Sir Thomas Gresham are free to the public and no tickets are required.

ARMY OFFICER AND CITY CORPORATION.—Colonel R. J. Blackham, C.B., D.S.O., M.L., has been elected a member of the Court of Common Council of the City of London. There was a contest for the representatives of the Ward of Farringdon Without on St. Thomas's Day, and Colonel Blackham was second from the top of the poll. He is, we believe, the first retired officer of the regular Army Medical Service to become a member of the City Corporation.

AN ANCIENT SALOPIAN CUSTOM.—The 179th anniversary service of the Royal Salop Infirmary took place at Shrewsbury on Jan. 3rd. On this occasion the collection is made by two men and two women plate-holders. The men were described of old as "two gentlemen of distinguished rank and fortune," and the ladies are usually the latest bride of the "county" and a débutante at the Shrewsbury Hunt Ball, which takes place at about the same time. Formerly they wore their ball-dresses and the men their hunt uniform, but these customs have fallen into disuse.

THE LATE DR. D. A. O'SULLIVAN.—Daniel Aloysius Sullivan, M.D., who died at his house at Bath on Dec. 30th at the age of 82, qualified as L.R.C.S.Irel. in 1869 and L.R.C.P. Edin. and L.M. in 1873. After studying at the Catholic University, Dublin, where in 1868 he gained the gold medal for materia medica, medical jurisprudence, and practical chemistry, he practised in Cork, Burnley, Southport, and London. The degree of M.D. (hon. causâ) was conferred on him by the National University of Ireland. Dr. O'Sullivan was for many years a member of the Central Council and a vice-president of the Lancashire and Cheshire Branch of the British Medical Association.

ROYAL SUSSEX COUNTY HOSPITAL.—The John Howard wards, comprising 20 beds for the reception of patients who are charged not less than £3 and not more than £4 per week, have proved of considerable benefit to the class of patients for whom they were intended, as well as a lucrative source for the institution at Brighton. The two-year agreement between the trustees of the late Sir John Howard and the governors of the hospital, whereby the trustees undertook to pay to the hospital a sum of £2000 a year over and above the fees which the hospital was authorised to charge the patients, has expired, and the trustees are anxious to terminate their responsibilities. They have come to the conclusion that a trust of a permanent nature should be created, and that they are not justified in continuing to pay to the hospital so large an annual sum as £2000. An agreement has been reached whereby a capital sum of not less than £23,000 is to be transferred by the trustees to the Official Trustee of Charitable Funds to be held in trust for the Royal Sussex County Hospital. The income therefrom will be paid to the John Howard Trust Committee towards the permanent maintenance and upkeep of the present John Howard wards.

PROVISION FOR NON-PULMONARY TUBERCULOSIS IN LANCASHIRE.—The Lancashire County Council some time ago purchased Wrightington Hall, the uses to which the Hall and the estate was to be put being referred for consideration to the County Tuberculosis Committee, and a sub-committee has been discussing a report by Dr. G. Lissant Cox. At present there is no accommodation available for patients suffering from pulmonary and non-pulmonary tuberculosis combined, and more especially for the non-pulmonary condition. Such cases are not taken to pulmonary hospitals nor are they admitted to general hospitals. An institution with an up-to-date light installation would, it is thought, cure the patients suitable for this special form of treatment more quickly than do the methods at present in use. The whole of the accommodation required for the treatment of non-pulmonary cases—adults and children—could be, it is said, provided on the Wrightington Hall estate; and, in addition, 80 beds for adults and 110 for children suffering from combined pulmonary and non-pulmonary tuberculosis. Of these 220 beds, 110 would be replacements and 110 would be additional accommodation. Calculating the maintenance charge at £2 10s. per week, these additional 110 beds would entail a new gross expenditure of £15,080 per annum. After certain deductions from this amount, the cost would be about one-sixth of a penny on the rates. The Government grant of £180 per bed would be available for accommodation provided at Wrightington.

ROYAL INFIRMARY, EDINBURGH.—The annual report describes progress in the development of the radiological department and a reduction in the waiting-list, but states that the problem of better accommodation for nurses is still unsolved and is probably insoluble without the acquisition of more ground. The total number of patients treated in the year ending last September was 15,755, and the average time each patient was treated was 20.6 days. The average waiting-list for admission was 1032, and 55,340 cases were treated in the out-patient department. The ordinary expenditure was £137,750, and the cost per occupied bed is estimated at £141.

MESSRS. W. Heffer and Sons, Ltd., Cambridge, hope to publish in February the seventh edition of Mr. S. W. Cole's "Practical Physiological Chemistry." This edition has been considerably revised and enlarged, and two new chapters on biological oxidations and reductions and on the analysis of blood have been added.—Amongst the publications announced by Mr. Henry Kimpton, High Holborn, London, W.C. 1, are "Bacterial Infection: with special reference to Dental Practice," by Prof. J. L. T. Appleton, of the University of Pennsylvania; "The Therapy of Puerperal Fever," by Dr. Robert Koehler, of Vienna; "A Text-book of Physiology" (second edition), by Prof. W. D. Zoethout, of the Chicago College of Dental Surgery; "Asthma and its Radical Treatment" (second edition), by Dr. James Adam; "A Descriptive Atlas of Visceral Radiograms," by Mr. A. P. Bertwhistle and Mr. E. W. H. Shenton; and "An Introduction to Clinical Perimetry," by Mr. H. M. Traquair.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

THURSDAY, Jan. 14th.—4.30 P.M.—The following papers will be read:—Leonard Hill and Y. Azuma: Effects of Ultra-Violet Radiation upon Involuntary Muscle and the Supposed Physiological Interference of Visible Rays. I. de B. Daly: A Closed Circuit Heart Lung Preparation. Effect of Alterations in the Peripheral Resistance and in the Capacity of the Circulation. (Communicated by Prof. E. H. Starling.) *Papers to be read in title only:* T. S. P. Strangeways and Honor B. Fell: Experimental Studies on the Differentiation of Embryonic Tissues growing in vivo and in vitro. I. The Development of the Undifferentiated Limb-bud (a) When Subcutaneously Grafted into the Post-Embryonic Chick, and (b) When Cultivated in vitro. (Communicated by Sir William Hardy.) C. N. Long: Muscular Exercise, Lactic Acid, and the Supply and Utilisation of Oxygen. Part XIV. The Relation in Man between the Oxygen Intake during Exercise and the Lactic Acid Content of the Muscles. (Communicated by Prof. A. V. Hill.) K. F. Hetzel and C. N. Long: The Metabolism of the Diabetic Individual during and after Muscular Exercise. (Communicated by Prof. A. V. Hill.) W. G. Millar: The Diffraction Method of Measuring the Diameter of Erythrocytes. (Communicated by Sir E. Sharpey Schafer.)

### ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

**Tuesday, Jan. 12th.**

THERAPEUTICS AND PHARMACOLOGY } at 5 P.M.
MEDICINE
*Discussion:*
The Treatment of Pulmonary Tuberculosis with Sanocrysin.
*Openers:*
Prof. Elliott and Prof. Cummins.
The following have promised to contribute: Prof. Fraser, Dr. Tattersall, Dr. G. Marshall, and Prof. Murray Lyon.

PSYCHIATRY: at 8.30 P.M.
*Paper:*
Dr. R. M. Stewart: The Problems of the Mongol.

**Wednesday, Jan. 13th.**

SURGERY: SUB-SECTION OF PROCTOLOGY: at 5.30 P.M.
*Paper:*
Dr. Cuthbert Dukes: Simple Tumours of the Large Intestine and their Relation to Cancer.
A discussion will follow in which Sir John Bland-Sutton, Sir Lenthal Cheatle, Dr. Archibald Leitch, Dr. G. Marshall Findlay, Mr. Lockhart Mummery, and others will take part.
A demonstration of specimens and microscopic preparations will be on view after 4.30 P.M.

PATHOLOGY: Members of the Section of Pathology are specially invited to attend this meeting.

**Thursday, Jan. 14th.**

NEUROLOGY:
Clinical Meeting at the Hospital for Epilepsy and Paralysis, Maida Vale, at 8 P.M.

**Friday, Jan. 15th.**

ELECTRO-THERAPEUTICS: at 8.30 P.M.
Papers:
Dr. Justina Wilson: Treatment of Lupus by Ultra-Violet Light from Mercury-vapour Arc.
Dr. J. F. Brailsford: The X Ray Diagnosis of Animal Parasites (Helminths) found in Man.
Dr. J. R. Parry: Œsophageal Conditions.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Jan. 11th.—8 P.M., Pathological Evening. Exhibition of Specimens and Skiagrams.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Jan. 11th, to FRIDAY, Jan. 15th.—BETHLEM ROYAL HOSPITAL, S.E. Lecture-demonstrations in Psychological Medicine at 11 A.M. Tues. and Sat., Dr. Porter Phillips and Dr. Thomas Beaton: The Psychoses.—NORTH-EASTERN FEVER HOSPITAL, St. Ann's-road, Tottenham. Wed., 2.30 P.M., Sat., 11 A.M., Dr. Frederic Thomson: Demonstration in the Diagnosis and Treatment of the Acute Infectious Diseases.—ST. MARK'S HOSPITAL, City-road, E.C. Mon., 5 P.M., Mr. Lockhart-Mummery: Special Clinical Demonstration.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Special Course in Nervous Diseases. Mon., Dr. Yealland: Hemiplegia and Paraplegia. Tues., Dr. Hildred Carlill: Lesions of the Peripheral Nerves. Wed., Mr. Rea: Ocular Manifestations of Nervous Disease. Thurs., Dr. Yealland: Disseminated Sclerosis. Fri., Dr. Worster-Drought: Clinical Forms of Neuro-Syphilis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE. Prince of Wales's General Hospital, Tottenham, N.
Intensive Course: Daily, 10.30 A.M. to 1 P.M., Demonstration of Clinical Methods. 2 P.M. to 4 P.M., Selected Cases and General Hospital Work. 4.30 P.M., Clinical Lectures.
MONDAY, Jan 11th.—Dr. Eric Pritchard: Principles of Nutrition.
TUESDAY.—Dr. F. G. Crookshank: Diseases of the Mediastinum.
WEDNESDAY.—Dr. A. E. Giles: Endocrines in Gynæcology.
THURSDAY.—Dr. C. E. Sundell: Feverish Attacks in Childhood.
FRIDAY.—Mr. H. W. Carson: Hæmatemesis.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.
THURSDAY, Jan. 14th.—5 P.M., Mr. A. W. Bourne: Maternal Mortality.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.
WEDNESDAY, Jan. 13th.—Dr. Harrison: Urinary Deposits, Calculi and Concretions.
THURSDAY.—4 P.M., Dr. Frew: Enuresis.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Jan. 12th.—5 P.M., Dr. Haldin-Davis: Pruritus. Prurigo. Lichenification.
THURSDAY.—5 P.M., Dr. H. G. Adamson: The Erythemata.

ROYAL INFIRMARY, Sheffield.
FRIDAY, Jan. 15th.—3.30 P.M., Dr. Rupert Hallam: The Differential Diagnosis of Small-pox and other Skin Diseases.
Demonstration of Some Common Skin Diseases.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.
FRIDAY, Jan. 15th.—4.30 P.M. (at Whitworth-street West Branch), Dr. J. F. Ward: Examination of the Chest in Children.

# Appointments.

ALDRED, CHARLES N., M.B., Ch.B. Manch., has been appointed Casualty House Surgeon, Salford Royal Hospital.

ASH, E. BAYLIS, M.B., Ch.B. Birm., M.R.C.P. Lond., Honorary Assistant Physician to the Birmingham and Midland Skin Hospital.

CRITCHLEY, ELIZABETH E., M.B., Ch.B. Edin., Assistant Medical Officer of Health, Preston.

GEBBIE, N., M.D., Ch.B. Glasg., D.P.H., Medical Officer of Health, Stockport.

PASSEY, R. D., M.B., B.S. Lond., Lecturer at the Welsh National School of Medicine, Cardiff.

THOMAS, D. E., M.R.C.S., L.R.C.P., House Surgeon at the Carnarvonshire and Anglesey Infirmary, Bangor.

WEAVER, R., M.B., B.Ch. Belf., D.P.H., Medical Officer and School Medical Officer, Tipton District Council.

St. Andrew's Hospital, Dollis-hill, London, N.W.: HILL, N., M.D. Lond., Honorary Assistant Physician; McCULLAGH, W. McK. H., M.B., B.Ch. Belf., F.R.C.S. Eng., Honorary Assistant Gynæcologist.

Certifying Surgeons under the Factory and Workshop Acts: FARMER, M. L., M.B., Ch.B. Liverp., Croston, Lancs; COX, R., M.B., B.Ch. Camb., Yeovil; FINDLAY, J., M.B., Ch.B. Aberd., Peterhead, Aberdeen.

# Vacancies.

*For further information refer to the advertisement columns.*

*Barrow-in-Furness County Borough.*—Asst. M.O.H. and Asst. Tub. O. £600.
*Birmingham General Hospital.*—Med. Reg. and Res. M.O. £155.
*Birmingham and Midland Eye Hospital.*—Res. Surg. O. £150.
*City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.*—H.P. At rate of £100.
*Canterbury, Kent and Canterbury Hospital.*—Hon. S.
*Colchester, Severalls Mental Hospital.*—Asst. M.O. Locum Tenens, 7 guineas weekly.
*Derby County Borough.*—Asst. M.O. £600.
*Derbyshire Royal Infirmary, Derby.*—Ophth. H.S. £200.
*Hatton, Warwick County Mental Hospital.*—Jun. Asst. M.O. £250.
*Herefordshire General Hospital.*—H.S. Also Second Resident. £150 and £100 respectively.
*Hospital for Consumption and Diseases of the Chest, Brompton, S.W.*—H.P. £50.
*Ilford Urban District Council.*—Chief Asst. M.O.H. £700.
*Kent Education Committee, School Medical Service.*—Dentist. £500.
*Lambeth Parish Board of Guardians.*—Public Vaccinator.
*Leeds Public Dispensary.*—Sen. Res. M.O. £200.
*Lenham Sanatorium.*—Asst. M.O. £400.
*Lincoln County Hospital.*—Sen. H.S. At rate of £200.
*London Fever Hospital, Islington, N.*—Sen. Res. M.O. £500.
*London Lock Hospital, 283, Harrow-road, W., and 91, Dean street, W.*—Hon. Surg. to Out-patients. Also Hon. P.
*Macclesfield General Infirmary.*—Second H.S. £150.
*Manchester, Ancoats Hospital.*—H.P. At rate of £100.
*Metropolitan Asylums Board Infectious Hospitals Service.*—Med. Supt. £900.
*Metropolitan Hospital, Kingsland-road, E.*—Asst. P.
*Middlesex County Council Sanatorium, Harefield.*—Third Asst. Res. M.O. £400.
*Middlesex Hospital Medical School, Dept. of Physiology.*—Research Asst. £250.
*Nottingham, Bagthorpe Institution and Infirmary.*—Asst. Res. M.O. At rate of £300.
*Oswestry, Shropshire Orthopædic Hospital.*—H.S. £200.
*St. Andrew's Hospital, Devons-road, Bow, E.*—Med. Supt. £700.
*St. Helens Hospital, Lancashire.*—Res. M.O. £250.
*Shanghai Municipal Council, Public Health Dept.*—Asst. Health O. Tls.700 per mensem.
*Sheffield, South Yorkshire Mental Hospital.*—M.O. £400.
*Southport Convalescent Hospital and Sea-Bathing Infirmary.*—Res. Med. Supt. £600.
*Sudan Medical Service.*—Four M.O.'s £E.720.
*Victoria Hospital for Children, Tite-street, Chelsea, S.W.*—H.P. and H.S. Each at rate of £100.
*West London Hospital, Hammersmith-road, W.*—Hon. Obstet. Reg.

The Chief Inspector of Factories, Home Office, London, S.W. announces vacancies for Certifying Factory Surgeons a Ryde, Isle of Wight; Rothwell, Yorks, West Riding Alton, Hants; and at Tetbury, Glos.

# Births, Marriages, and Deaths

## BIRTHS.

HIBBINS.—On Dec. 31st, 1925, at "Restholme," Boxhill-on-Sea the wife of W. R. Hibbins, L.D.S., of a daughter.

STUART-WEBB.—On Jan. 4th, at Sussex House, Sutherland avenue, W., the wife of R. E. Stuart-Webb, M.B., of a son

## MARRIAGES.

GROSS—MACDONALD.—On Dec. 29th, 1925, at Holy Trinity Brompton, William Stovell Gross, M.D., M.R.C.P., to Mrs Dorothy Francesca Macdonald, daughter of the late Harol Holden-White.

## DEATHS.

DODD.—On Dec. 27th, 1925, at a nursing home in London Brevet Colonel Anthony Dodd, late R.A.M.C., of Windycroft Instow, N. Devon.

HALLOWS.—On Dec. 29th, 1925, at his residence, Hall gate Doncaster, Harry Pinnington Hallows, M.D. Edin., F.R.C.S. Knight of Grace, Order of St. John of Jerusalem, aged 68

HAMPSON.—On Jan. 1st, at his residence, Royal-crescent Holland Park, W., William Hampson, L.M.S.S.A. Lond (formerly of West Rock Ferry).

HARCOURT.—On Dec. 29th, 1925, suddenly, at St. Thomas' Hospital, John Charles Harcourt, M.B., D.P.H., aged 5 years.

KENT.—On Nov. 24th, 1925, at Tongshan, North China, Hug Braund Kent, F.R.C.S. Eng., M.S. Lond., fourth son o Horace Kent, Barrister-at-Law, and dearly loved husban of Margaret Kent, aged 43 years.

MILLS.—On Dec. 28th, 1925, at Riverdale-road, Sheffiel Lieut.-Colonel Bernard Langley Mills, M.D., F.R.S.E R.A.M.C. (retd.)

MOORE.—On Dec. 28th, 1925, at Elmside, Steyning, Sussex, D Frederick Hone Moore.

O'SULLIVAN.—On Dec. 30th, 1925, at his residence, Glencair House, Bathwick, Bath, Daniel Aloysius O'Sullivan, M.D. Catholic University, Dublin, late of Cork and Burnley, ag 83 years.

WINSTANLEY.—On Dec. 31st, 1925, suddenly, at his residence Half Moon House, Haslemere, Robert Wyndham Winstanley M.R.C.S., L.R.C.P., L.S.A., aged 67.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices o Births, Marriages, and Deaths.*

## THE HISTORY OF ANTHRAX IN THE WOOL INDUSTRY OF BRADFORD, AND OF ITS CONTROL

By F W Eurich, M D Edin,

SENIOR HONORARY PHYSICIAN ROYAL INFIRMARY BRADFORD, PROFESSOR OF FORENSIC MEDICINE, UNIVERSITY OF LEEDS, AND FORMERLY BACTERIOLOGIST TO THE LATE ANTHRAX INVESTIGATION BOARD FOR BRADFORD AND DISTRICT

(*Concluded from p 55*)

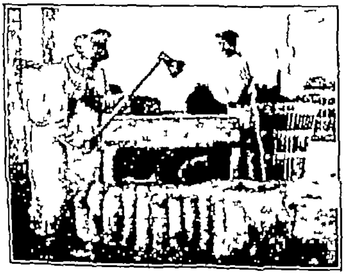
[In the earlier part of this paper *Dr Eurich* told the story of the discovery of the cause of woolsorters' disease and of the early measures taken for its prevention up to the issue of the Home Office regulation in February, 1897 The four illustrations which now accompany the conclusion of the story show the various processes of wool-sorting in which infection may occur ]

The statutory regulations of 1897 having been tried for eight years without any consequent effect upon the incidence of anthrax, a revision of wool-sorting and wool-combing rules was deemed necessary These revised rules, in force to-day—with certain additions, the outcome of the work of later years—were published in December, 1905 During the discussions at the meetings of the joint committee of representatives of the Bradford Chamber of Commerce and the Operatives Associations, it was suggested that a committee should be formed "for the purpose of determining more precisely the classes of wool and hair in connexion with which the danger of anthrax arises, and to consider further means of prevention." This proposal was accepted and so, under the auspices of the Chamber of Commerce, with the coöperation of the Home Office, the Anthrax Investigation Board for Bradford and District came into being, and I was asked to conduct the medical and bacteriological parts of its work.

### *Culture of the Bacillus*

The area over which the investigations were to extend was at first restricted to the worsted industry of the West Riding comprising Bradford, Keighley, Bingley, Queensbury &c. Batley, Dewsbury, and Mirfield were included later So the work began I do not know whether you can realise with what consternation I looked upon the hundreds of bales, each weighing 3 cwt. or more, which filled the warehouses of the mills to which the chairman took me. Where was I to begin, and what method should I adopt? Fortunately for me the question was decided for me, hand-samples being sent to me by various firms in connexion with cases of anthrax, which were at just that time of almost weekly occurrence Anthrax had not previously been cultivated from wool and hair, the few positive results which had been obtained elsewhere than in Bradford having been the outcome of inoculation experiments. Such a method was impracticable here In the first place, the health committee would not allow its premises to be licensed for vivisection, so that all inoculations had to be carried out by me in the pathological department at Leeds. Secondly, so numerous were the samples to be tested that a small menagerie would have been needed to harbour the animals, and the sacrifice of animal life would have been too great. "You won't find anthrax in the raw material," Bell said to me, when I mentioned the problem to him, and I think it was more by good luck than good management that I succeeded—during the first year—in isolating anthrax bacilli from two samples of Persian wool and from one sample of dust from Persian wool out of a total of 123 samples The prime difficulty was this: Anthrax colonies upon gelatine or agar are said to be typical, being composed of masses of curling filaments resembling a barrister's wig; this description is certainly an apt one, but the appearance is not typical, and I soon found that other dust organisms will grow so fast upon agar and may form so dense and widespread a pellicle on its surface that the colonies of anthrax are crowded out or covered by them

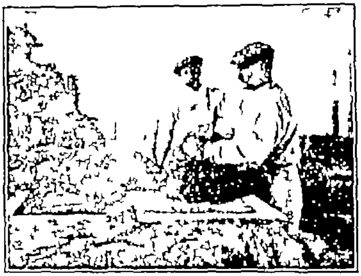
FIG. 1



Opening of bale of wool

After a variety of experiments, with the details of which I will not weary you, I found that the most characteristic form of anthrax colony is obtained by cultivating the bacillus within the agar jelly, not on its surface By adding a wash from the sample of hair to a sufficiency of melted agar (about 9 c.cm. to a plate 4 in in diameter is a workable quantity) the majority of organisms present will be scattered below the surface and the resulting colonies will remain small and fairly well distinct from each other A deep anthrax colony, seen with the naked eye or a pocket-lens, is not unlike the *tell tale filaments* seen in the urine from a case of gleet, and with higher magnification resolves itself into a tangle of knotted strands. Applying this method of cultivation to washes made *from* wool and hair some surprising results were obtained

FIG 2



Opening the fleeces.

### *Recognition of Contaminated Hides.*

It had hitherto been supposed that the dirtier and the more offensive the wool, the greater the danger This is erroneous. Wool and mohair washed beautifully clean, and of silky lustre, may yet have retained their deadly properties. This explains the occurrence of anthrax among those who manipulate wool in processes subsequent to washing The fact that the anthrax bacillus was often obtained from these clean samples in almost pure culture suggested the existence of a hitherto unconsidered factor in the infection of the raw material. This factor is the blood of the animal, be it derived direct from the blood-stream or from blood-stained discharges It is the adhesive property of the blood which is of the greatest importance; soil and excrement are easily removed from the fleece in its rapid passage through the wash bowl, but the dried serum will adhere and with it the anthrax spores

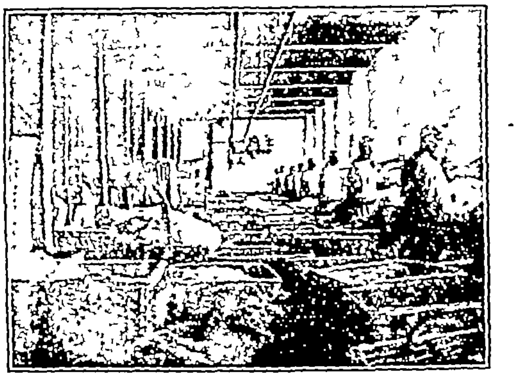
An interesting fact is worth recording I found on one occasion that a 5 g sample of mohair containing more than 100 000 aerobic organisms contained, after washing and drying, only a few hundred, yet the number of anthrax colonies remained relatively high, thus illustrating the tenacity with which blood serum adheres to the material. Furthermore, hairs and soil become glued together to form hard, compact, brittle masses very difficult to penetrate by water and by disinfectants.

Bearing these facts in mind we can understand why the wool-sorting and wool-combing regulations have failed to do more than offer some measure of protection to the sorters. The instruction to remove all damaged and "fallen" fleeces —i.e., fleeces taken from the dead animal—can be effective *only if* the opener or sorter knows their distinguishing characters. As a matter of fact, not a single opener or sorter possessed this knowledge prior to 1908 A fleece was *considered to be a fallen* one when of a peculiar dead lack lustre appearance, an appearance due to prolonged exposure after death. The longer the exposure the more advanced will be the decomposition of the carcass; but as the bacillus of anthrax perishes as putrefaction advances the so-called fallen fleece will be less dangerous the more characteristic its appearances are.

As for the steeping of bales, its futility from the point of view of the carder and comber is sufficiently obvious, the wool being dry again when it comes to his hands, while fans will remove only the loose dust, leaving the dry serum adhering to the fibre. The inefficacy of washing has already been dealt with.

The regulation demanding the exclusion of fallen fleeces had therefore to apply to all blood-stained material, even though some of it may have been derived from healthy animals. Such a precaution had, of course, its limitations. It was soon found that anthrax colonies could be obtained from wool and hair, sometimes even in large numbers, on which no trace of blood could be seen. On inquiry it was found that these wools had either been fellmongered, or had, like East Indian wools, been washed in the country of export—i.e., the danger-signal had been removed while this infection remained and had in all probability spread to fleeces previously sound. It is, however, only fair to state that in a few instances anthrax bacilli were cultivated from wool which showed no evidence of contact with water.

FIG. 3.



Sorting wool.

### *Nature and Source of Infected Goods.*

What wool and hair have been found infected? The samples examined by me number close upon 14,000. They comprise alpaca, mohair from Turkey, Lake Van, and the Cape; Persian wools, Egyptian, Syrian, and Cape wools; East Indian wool and East Indian goat-hair; goat-hair from Tunis and other parts of the Mediterranean; cashmere; Chinese goat-hair, Chinese camel-hair, and Russian camel-hair, besides occasional samples of English, Scotch, Australian, and South American wools. To work out a list in the order of danger is very difficult, the degree of infectivity of these materials varying in different years even when imported from countries in which anthrax is endemic. I have sometimes found only a small percentage infected, at another a vastly greater number. Thus on one occasion I found 11 out of 13 samples of Turkey mohair tainted; on another, of 78 samples of Cape skin mohair, 42 were infected. Taking all in all, I think that East Indian goat-hair is an easy first with approximately 30 per cent. positive results, closely followed by East Indian cashmere and Egyptian wool; then follow Persian wool, East Indian wool, and mohair. In addition we must consider Syrian wool, Tunisian and Mediterranean wool, and Chinese wool and goat-hair and alpaca dangerous. How can all these raw materials be rendered innocuous? That was the remaining problem which the Anthrax Board set itself.

### *Methods of Disinfection.*

Would that the problem had been as easy as it was imagined to be by a dear old fellow who invaded my laboratory one afternoon to explain to me his method. "It's very simple," he said, "to kill the anthrax insects; just pass the wool between heavy iron rollers and squash the beggars." Heat, wet or dry, was found useless, as was expected; if high enough to kill the spores it also damaged the wool irretrievably. We were therefore thrown back upon chemical disinfection. A disinfectant to be commercially possible has to fulfil three requirements: (1) it must kill all anthrax in all wool or hair; (2) it must not be noxious to the workers; and (3) it must be economical both of time and money. Of all the disinfectants tried only one—viz., formaldehyde—answered these requirements. It was found that a 2 per cent. solution would, at a temperature of 100° F. kill naked anthrax spores in 30–35 minutes. Two factors, however, militated against its success in practice. In the first place minute quantities of air caught between the wool fibres would tend to prevent the solution from reaching all parts of the material treated. Secondly, formaldehyde will harden the albuminous constituents of blood clots, and this hardening of the outer parts of the clot will naturally impede penetration. Rough tests had previously shown that formaldehyde does not seriously interfere with either the spinning or the dyeing property of wool; nor did it seem likely that the irritant properties of formalin would prove an obstacle difficult to overcome.

At this point a second investigating body took up the problem of disinfection. In November, 1913, a Departmental Committee had been appointed by the Home Office to inquire into the dangers from infection by anthrax in the processes of wool-sorting, wool-combing, &c., and to consider and report whether any, and if so what, amendments were desirable in the regulations for these processes. This Committee, of which I was a member, came to the conclusion that no amendments to the regulations were likely to affect the incidence of the disease, and so, going beyond its terms of reference, it appointed a small subcommittee to consider the problem of disinfection. The secretary to the Committee and of its subcommittee was one of H.M. Inspectors of Factories, Mr. Elmhirst Duckering. It is not too much to say that it is due to his energy and practical genius that the difficulties mentioned have been overcome. As a member of the subcommittee I enjoyed the inestimable advantage of working with him, the experiments being left in his hands and in mine. The report of this subcommittee is published separately as a Blue-book, and fills 92 closely-printed folio pages. The experiments were carried out with both naturally infected material—viz., clots from Persian fleeces and with artificial clots. 149 experiments were made. The difficulties were finally overcome by the adoption of three devices: (1) In order to gelatinise and soften the clots the opened wool is passed through warm water to which alkali has been added and then through a further bath containing soap. (2) To ensure that minute air bubbles may not be retained in the meshes of the wool, and in order to break up the softened clots as much as possible the wool is squeezed between rollers in its passage from one bath to the next, and this process is repeated as the wool passes into the formaldehyde bath—which is enclosed in a chamber. (3) The third device consists in drying the wool, which again passes between a set of rollers as it emerges from the formaldehyde bath to travel upon a moving lattice to the drying chamber.

FIG. 4.

Feeding the willey machine.

### *Advantages of Formalin.*

Here we may note the use to which a common cold may be put. Mr. Duckering caught a cold; in order to cut it short he poured some formalin upon his handkerchief on going to bed. He was astonished to find on the following morning that though the handkerchief was dry the odour of formaldehyde was still distinctly perceptible. This gave him an idea, and it was found by experiment that formalin would continue to penetrate the remains of blood-clots after removal of these from the bath and that, when the dried wool has been stored for two, or at most three days, the formalin will have done its work, even the most resistive spores being killed. Over 1500 control tests carried out by three independent examiners—by our city bacteriologist, in the Liverpool Public Health Laboratory, and by myself—have shown that the method is effective and reliable. The Government disinfecting station in Liverpool is the result. It is at present the only one in the kingdom and is still regarded as a trial station. But the work it does is great; 1600 lb. of wool can be disinfected in an hour—i.e., the present plant is capable of disinfecting about 10–12,000,000 lb of wool and hair per annum if kept fully employed.

The Anthrax Prevention Act provides that an Order in Council may prohibit the importation of dangerous material except on the condition that it is disinfected in the Government wool disinfecting station. Up to the present such an Order in Council has been made to apply to two materials only—viz.: (1) to wool and hair imported from or through Egypt, and (2) to goat-hair imported from or through India. The present total import of these two classes of material is about 2,000,000 lb. yearly, while about another 500,000 lb of wool is sent voluntarily to the station for disinfection. As, however, about 20,000,000 lb. of scheduled or black-listed raw material are imported into this country annually it follows that cases of anthrax will continue to occur until all dangerous wool is sterilised or until effective precautions are taken in the country of origin.

One reason for the reluctance of manufacturers to make use of the Liverpool disinfecting station voluntarily is the cost of the process. The cost of disinfection—which is chargeable to the owner of the wool—varies from 1d. to 1½d. per pound, and may be lowered still further when means for the recovery of formaldehyde shall have been completed. The cost is a small one, but competition is keen, and even an additional 1d. per pound on the cost of production may hamper our manufacturers in the world-market.

International coöperation is called for and has indeed been discussed by the League of Nations, hitherto, unfortunately, without success.

The pebble which Bell cast into the water has raised a wave that has travelled and is being felt even in distant China and Peru. Let us trust that the principle which guided him throughout his professional life will be shared by the Governments concerned, and that the relief and prevention of suffering, even if it affect but the few, will in the end prevail over subsidiary considerations.

## THE TROUBLESOME CHILD.

UNDER the auspices of the Jewish Health Organisation, Dr A. R. Abelson delivered, on Dec. 26th, at the Whitechapel Art Gallery, London, an address on delinquent children.

Although much progress has been made, he said, the existing system for reforming wrong-doers leaves a great deal to be desired. Wrong-doing is largely bound up with morbid conditions of mind and body, and not everyone is given full power to discern between right and wrong. An important percentage of delinquents are mentally defective, and hence, as a rule, morally deficient; but probably a still larger number are suffering from functional nervous disturbances for which psychological treatment can effect considerable improvement, especially where the moral instability goes hand in hand with what is generally termed a neurotic constitution. These children are often sensitive to good influence, and under ordinary circumstances they are well disposed. Physical disorders must also be taken into serious consideration and receive treatment. After encephalitis lethargica, for instance, a child hitherto extremely well behaved and tractable may develop alarming immoral behaviour. Such conditions as tuberculosis and heart disease are also capable of causing moral upheaval leading to vice and immorality.

### *The "Naughty Child."*

A large number of children often spoken of as fidgety, restless, and inattentive at school are suffering from minor nervous disorders. Teachers can frequently testify to the improvement brought about by removal or cure of diseased tonsils or by the correction of defective vision or hearing. All human beings are potential delinquents. "Surely there is not a righteous man on earth who doeth good and sinneth not" was wisely said by the preacher of old. It is for us to find out the causes of wrong-doing and how it can be remedied, and still more important how it can be prevented. Mr Clarke Hall, magistrate of the Children's Court at Old-street, strongly emphasises the amazing number of young people committing offences, often serious and repeated, who are never brought before a court, either because they are so cunning in concealing their repeated offences or through the reluctance of their parents to expose unpleasant misdeeds. These cases alone show the crying need for some institution where parents who are in trouble can come for advice about their children, which can be given in the strictest confidence without the danger of exposure. A parent who has a nervous child—perhaps a well-behaved child who sleeps badly or has a morbid terror of the dark—could also come there for advice and save considerable heart weariness in years to come. And it is much more necessary to have some such institution where parents can bring their delinquent children before public disgrace has occurred. The common way of attempting to cure children of nervousness and other peculiar weaknesses by shouting, laughing at them, and by making them appear foolish is strongly to be deprecated. It only aggravates evils which require kind treatment and sympathetic help. Strict and narrow upbringing may lead from lying and deceit to hypocrisy and secret consorting with morally unhealthy companions; from tacit disobedience to open rebellion. Wrong-doing is merely a symptom, and as such it cannot be spoken of as being inherited; but criminal acts are more likely to arise where the soil is favourable, and more criminality may be expected in stocks which produce mental defectives or show other signs of marked abnormality than in normal families.

### *Environment and Family.*

Improvement of environment is bound to decrease the amount of delinquency by reducing facilities in our crowded towns for immorality and vice. Homeless young people who are out of work, and even those who are in work, should be able to go to hostels if stranded. Parent and child should alike be educated to meet the problems and dangers of life intelligently. Spoiling and pampering of the eldest child, the only child, or the youngest child, leads to nervous disturbance besides disobedience, bad temper, conceit, and selfishness. Favouritism induces jealousy and resentment in the other members of the family, and unjust accusation may lead to lifelong unpleasant memories. The child, especially, who is inclined to imagine that he is unjustly treated by parents or teachers, requires more careful handling than the average parent—and in particular the tired and harassed mother of a large family in conditions of poverty—is capable of bestowing. Yet the real difficulty is not so much in the external and obvious defects of the home, such as poverty and neglect, as in the inner complicated tangle of habits, attitudes, and reactions that have grown up in the minds of the more active inmates.

In the past said Dr Abelson, the Jews have played an important part in the fight for humane and rational treatment of the erring child. The Jewish industrial schools and reformatory can produce an excellent record of achievement. Further progress, however, lies in the provision of greater scope to medical men and psychologists and in substituting the atmosphere and methods of the clinic for those of the court and prison.

## HEALTH OF PALESTINE UNDER THE MANDATE.

IN the report for 1924 on the administration under mandate of Palestine, the following references are made to health matters. The year was marked by a notable advance in the control of malaria and trachoma; by a beginning in pilgrim quarantine on the Hejaz and Sinai railways; and by the extension of the movement for municipal participation in the conduct and cost of local hospitals. Save in Jerusalem, Tulkarem, Acre, and Haifa the end of the year saw local hospital committees everywhere constituted to direct at their own charge the non-technical services of the hospitals founded and hitherto entirely maintained by Government. Measles is again responsible for a higher death-rate; little can be done to prevent the spread of this disease or to provide medical and nursing aid. Typhoid, typhus, and dysentery affected only the Jewish population, but with low incidence. In the Metullah salient, before general vaccination could be practised, there was an outbreak of small-pox with 17 cases among an isolated Bedu tribe. Four cases occurred in Jaffa among Yemenite immigrants. 54,001 persons were vaccinated by medical officers. Malaria is progressively less prevalent, as is indicated by the percentage of dispensary patients treated for the disease; in 1922 this was 7·3 per cent., in 1923 4·0 per cent., and in 1924 3·8 per cent. In nine months of 1918 118 persons died in Jerusalem from malaria; in 1924 only two. Acute conjunctivitis was rife in 1924. Of 12 projected Government ophthalmic clinics to operate by the generous arrangement of the Order of St. John under the supervision of the Warden and the British Ophthalmic Hospital, Jerusalem, those in Nablus, Ramleh, Gaza, and Beersheba are already in existence; 60,000 school-children were kept under medical observation for trachoma. Two cases of bubonic plague occurred in Jaffa. Acute poliomyelitis and cerebro-spinal fever were reported in two and three cases respectively; tuberculosis in 479 cases with 103 deaths; schistosomiasis in 28 cases, 21 being in Jaffa district, where this disease is endemic. There were nine cases of hydrophobia in untreated cases;

antirabic measures were energetically practised by the Departments of Health, Agriculture, and Police, and over 8000 dogs and jackals destroyed by strychnine bait in the first nine months of the year. Up to the end of October 25,352 births and 14,213 deaths had been recorded, increases of 3928 and 836 respectively over the corresponding period of 1923. Two thousand Palestinians made the pilgrimage to Mecca and 2502 Moslem pilgrims of other countries visited the holy shrines in Palestine, including some 600 who came overland. The Quarantine Board of Egypt has undertaken to establish a station at El Arish for the mutual protection of Egypt and Palestine should either country become infected. Nineteen pupil nurses passed their qualifying examination, and nine pupil midwives, trained at the Princess Mary Maternity Centre, were granted certificates. Ninety licences to practise were granted to doctors, 16 to pharmacists, 36 to dentists, and 31 to midwives. The adhesion of Palestine to the International Opium Convention was notified by His Majesty's Government in August. Twelve kilogrammes of opium, 615 of morphine, 4137 of cocaine, and 125 of heroin were imported under permit; several contraband consignments of dangerous drugs were seized. In the Government laboratories 18,000 routine examinations were made. The chemical laboratory has engaged in research relating to the recovery of potash from Dead Sea brine. 21,000 doses of antirabic vaccine were prepared and 819 persons treated. Antityphoid and anticholera vaccines have also been manufactured for use among immigrants and pilgrims.

## TRAINING TEACHERS OF DEFECTIVE CHILDREN.

In recent years many classes have been opened for dull and backward children, as well as special difficulty classes. The number of teachers with special training and qualifications is very small, and most local education authorities are obliged to choose for the work members of their school staff whom they think would be suitable. But the ordinary elementary school teacher should not be placed in charge of such a class without being given some training. The individual study of the children is necessary, and the ordinary class methods, with just a little more time given to manual work, are of very little use. The teaching of defectives is highly skilled work, demanding knowledge not included in the ordinary training college curriculum. The Central Association for Mental Welfare therefore organised last summer, with the full approval of the Board of Education, a training course, in which the needs of teachers of classes for the dull and backward and of special difficulty classes were specially catered for. The course was attended by 35 teachers, and was so successful that the Association is proposing to hold in London a similar course from May 3rd to July 3rd next, under the direction of Miss Lucy Fildes, educational organiser of the Association. It will not be in any way a substitute for the ordinary short courses organised by the Association for the Board of Education, two of which are being held this year. It is intended primarily for teachers with no previous experience of work for defective or backward children. Besides lectures on psychology and the medical aspects of the problem, opportunity will be given of observing the adaptation of ordinary methods of individual teaching to the special need of the defective child. The rôle of physical education and games in the development of the unstable and anti-social child will be carefully studied, and the best methods of grading the children will be demonstrated. Throughout the course teachers will be given chances of teaching groups of difficult children, of learning various forms of manual work, and of taking part in classes of eurhythmics. The fee will be 12 guineas and students will make their own arrangements for lodging. Applications must be sent, on a form provided, to Miss Evelyn Fox, 24, Buckingham Palace-road, London, S.W. 1, before Feb. 28th.

## WIND SCREEN TROUBLE.

*To the Editor of* The Lancet.

Sir,—Your motoring correspondent might have reminded his readers that any substance which lowers the surface tension of water can be applied to wind screens to banish raindrops. Bile salts are the substances par excellence which lower surface tension, but their application to the screen must needs be messy. The same objection can be raised against glycerine. For convenience, cheapness, and efficiency ordinary yellow soap is difficult to beat. It should be rubbed in irregular smears across the screen, and in a shower of rain a clear film of water, as wide as you please, soon appears. One application lasts all day. Apart from this particular use, a small cake of soap is always useful on a car. Raw potato and apple are all very well in their way, but they are not always instantly available. Any chemicals, however, applied to the screen are useless in snow or sleet.

I am, Sir, yours faithfully,

E. G. T. Liddell, B.M.

Trinity College, Oxford, Jan. 2nd, 1926.

## ALLEGED SMOKING OF STRYCHNINE IN CHINA.

Some months ago an article appeared in the *North China Daily News* alleging the extensive import of strychnine into China for use in drug smoking, and we have seen a more recent letter from a London firm of manufacturing chemists to Dr. W. H. Graham Aspland, of the International Anti-Opium Association, China (26, Hsi T'ang Tzu Hutung, Peking), stating that they had been shipping large quantities of strychnine nitrate (some of it labelled "for hunters' use"), but in view of disagreeable rumours as to the use to which it was being put they had decided to make no further sales to China for the present. Dr. Aspland writes of the import of 5000 ounces of strychnine salts monthly, "without the least restriction," and of the rapid increase of imported caffeine (chiefly to Shanghai and Hankow), amounting now to about 2000 lb. a month. The Chinese, he says, are mixing these alkaloids with heroin, cane-sugar, and milk-sugar in the manufacture of a pill of 4½–5 gr. in weight, the average formula being: Heroin hydrochloride 2¼ oz., strychnine nitrate ¼ oz., quinine sulphate 1 oz., caffeine 5 oz., sugar of milk 48 oz., refined sugar 16 oz., gum and water to make 10,000 pills. Dr. Aspland thinks that these pills are smoked like opium ("the new 'smoke' is more attractive"), but that the greater quantity are swallowed. Strychnine and caffeine are new to him as dope and he asks for enlightenment from pharmacologists as to the addictive effect of these drugs.

## A HANDBOOK ON DRINK.

The Year Book issued by the United Kingdom Alliance and edited by George B. Wilson is described as a temperance reformers' handbook, and contains an enormous amount of information on the problems arising out of alcoholism, and the conditions and interests which encourage the consumption of liquor. The Alliance is a "league of all good citizens whether abstainers or not, without distinction of party, sect or sex, united by a genuine desire to remove the evils of drink from the nation by removing their cause." It favours legislation to allow the people, on the widest possible franchise, to prohibit the sale of liquor in their own localities. It desires "to organise by democratic methods the wise exercise by the electorate of such power when obtained," and in the interval it is anxious to secure such general restrictions over the Liquor Trade as will in any way curtail its power and volume without entrenching it more firmly in the national life. The Year Book spends, perhaps, too much time in flogging horses generally admitted to be dead; but perhaps there are here and there owners who think there is life in them yet. And whilst it casts a proper light on the real motives of many of those who advocate an "improved public-house," it does not altogether meet the feeling of the man in the street that such places are possible and desirable. But the evidence which it does produce of national waste and inefficiency demands the fullest consideration of all those who are wondering how far personal liberty in the matter of drink should be given up to the good of the community, and the Year Book is almost indispensable for those occupied in social and political affairs. It may be obtained from the United Kingdom Alliance, 1, Victoria-street, London, S.W. 1, at the price of 2s.

## DIATHERMY AND OTHER ELECTRICAL APPARATUS.

Messrs. Newton and Wright (electro-medical instrument makers, 72, Wigmore-street, London, W. 1) send us interesting brochures on some of their recent specialties. The Holway diathermy apparatus is designed to suit either medical or surgical work, particular attention having been paid to the design of the spark gap. This consists of an aluminium chamber extensively ribbed on the outside, so that even with a large current it does not become unduly hot. This chamber is provided with an inlet and an outlet tap for gas dielectric, and can also be arranged for use with ether in cases where no gas supply is available. The actual gap comprises a large copper disc, heavily silvered, bridging over the space between a pair of heavy copper electrodes, likewise silvered, so that the gap is in duplicate, an arrangement which conduces to a steady current, while affording means of convenient and delicate adjustment. The electrodes, which are mounted on thick mica diaphragms, are provided with radiation fins for cooling. The Universal X Ray Table (1925 model) of the same firm appears to be a good piece of engineering enabling overhead or under-table work to be carried out with adequate protection to the operator. The brochure on ultra-violet therapy gives useful information in a modest compass, and illustrates several kinds of lamps which now find extensive application.

**Doncaster Royal Infirmary.**—Lord Cozens-Hardy last week opened the new ophthalmic department, which is very well arranged and equipped. The cost has already been met.

ON

# FOREIGN BODIES IMPACTED IN THE FOOD AND AIR PASSAGES

## MODERN TECHNIQUE IN THEIR DIAGNOSIS AND TREATMENT

*Delivered at the Manchester Royal Infirmary on Dec 11th and 18th, 1925,*

BY SIR W MILLIGAN, M D ,

CONSULTING SURGEON MANCHESTER EAR HOSPITAL CONSULTING AURIST AND LARYNGOLOGIST MANCHESTER ROYAL INFIRMARY

THE direct examination of the food and air passages by endoscopic methods has opened up a new chapter of great importance in the healing art both as to diagnosis and treatment Ever since Kirstein[1] in 1895 demonstrated the possibility of the direct examination of the laryngeal cavity by means of a special form of spatula with an attached lamp, the art of endoscopy has advanced by leaps and bounds

To the late Prof Killian in Germany, to Chevalier Jackson in America, to Guisez in France, and to Paterson, Tilley, Waggett, and others in this country, much of the knowledge in the possession of the profession of how to locate and how to extract impacted foreign bodies is due Each succeeding year has seen a greater degree of mechanical ingenuity and perfection in the manufacture of endoscopic instruments with a corresponding advance in the range of their therapeutic utility Not only is this true with regard to the diagnosis and treatment of foreign bodies impacted in the food and air passages, but also with regard to the many intricate problems connected with lung pathology Prior to the advent of endoscopy the death rate from foreign bodies impacted in the œsophagus was variously estimated at from 20 to 40 per cent., to-day it is barely 2 to 3 per cent. when the œsophagoscope is used.

In like manner the death rate from foreign bodies impacted in one or other portion of the bronchial tree has fallen from about 50 per cent. in pre bronchoscopic days to approximately 5 to 10 per cent. to-day In addition various pathological conditions—e g , bronchiectasis, pulmonary abscess, bronchial stenosis, &c —are to-day infinitely more amenable to successful treatment than was formerly the case To-day an endoscopic training and an endoscopic outfit form essential parts of a laryngologist s mental and manual armamentarium.

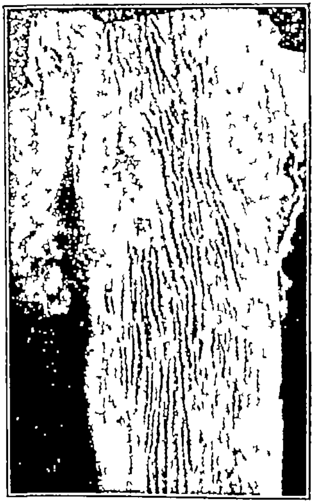
With the aid of expert radiography the presence of any opaque foreign body may be successfully determined and its location by means of antero-posterior and lateral roentgenograms accurately diagnosed With non-opaque or very slightly opaque objects the difficulties are enhanced, and when their presence is suspected but not ocularly demonstrated calls for a thorough physical, radiological and endoscopic investigation. The swallowing of a capsule filled with some opaque material may prove of assistance, being held up, as it usually will be at the point of obstruction, thus demonstrating the location of the intruder which may not be amenable to radiography The variety of foreign bodies which may be swallowed or inhaled is legion but those most frequently met with are pins, safety pins, coins, pencils, dentures, fruit stones, pea nuts, lentil beans, portions of toys, paper clips, small brooches pebbles, pieces of bone, nails, tacks, &c. The habit of putting various articles in the mouth, met with not only amongst children but also amongst those who ought to know better, is fraught with real danger on account of the ease with which they may slip down the food passage, or be inhaled during some sudden inspiratory effort.

### FOREIGN BODIES IN THE ŒSOPHAGUS

When impacted in the larynx death may ensue very rapidly from asphyxiation, when in the food passage, from subsequent ulceration with perforation into the aorta, pleura, or mediastinum. Fig 1 represents a perforation through the œsophageal wall into the aorta from a sharp piece of rabbit bone accidentally swallowed by a young woman Several minor attacks of hæmatemesis preceded the fatal issue, and on post-mortem examination the bone was found transfixing and perforating the aortic wall

The impaction of a foreign body in the œsophagus is usually accompanied by choking and gagging, but in children these symptoms may neither be noticed nor mentioned In adults subjective sensations of a foreign body being present may be complained of and should not be too lightly discarded When ocular inspection reveals nothing in the pharynx or lower pharynx the diagnosis should be regarded as incomplete pending a radiological and endoscopic examination

FIG 1



Perforation of wall of œsophagus by a piece of bone which also perforated the wall of the aorta

The practice of digital examination is to be condemned, the finger being prone either to push the foreign body farther down or to lacerate the soft tissues Inverting the patient should also be discouraged owing to the danger of subglottic impaction. Blind bouginage is equally reprehensible, the thin and movable œsophageal walls being frequently ruptured as a result. Should the cervical œsophagus be ruptured emphysema or abscess may result, while rupture in the thoracic area induces profound shock, emphysema, mediastinal suppuration, with at times perforation into the pleural cavity necessitating the performance of a thoracotomy for drainage purposes In such cases no attempt should be made to remove the foreign body until the rupture has had the chance of healing, but an immediate gastrostomy should be performed in order to feed the patient and to secure rest for the injured tissues.

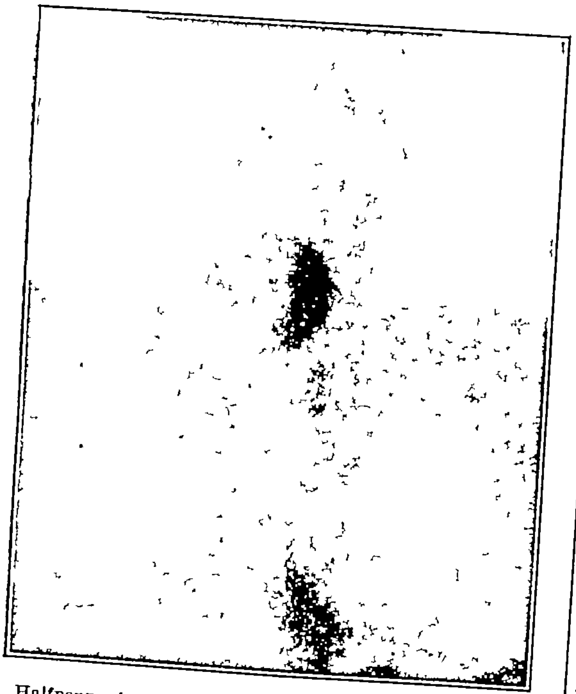
When a foreign body completely or all but completely blocks the œsophageal lumen, frothy secretion tends to collect in the pyriform sinuses (Jackson's sign) and to overflow into the larynx, inducing cough, huskiness, and even pulmonary symptoms. At other times pressure necrosis is induced with ultimate perforation and formation of an œsophagotracheal fistula or the escape of fluids into the pleural cavity or mediastinum. The sharper the foreign body the greater the risk of hæmorrhage or perforation, hence the danger of an impacted safety pin with the point pointing upwards. Damage may also be done to the larynx during attempts to remove a foreign body tightly wedged in the hypopharynx. Although a foreign body may remain impacted in the œsophagus for years, and may at times become encysted, its presence is always a source of danger owing to the risk of ultimate perforation of its walls.

---

[1] Deutsche Med Wochenschrift, 1895, No 38

Flat foreign bodies—e.g., coins—lie in the œsophagus in the coronal plane and usually at the level of the sterno-clavicular joint (Fig. 2), whereas if inhaled and impacted in the trachea they lie in the sagittal plane. The initial symptoms, choking, gagging, and retching, usually pass off after a short time, leaving, however, the sensation of "something" lodged in the throat.

FIG. 2.



Halfpenny in the œsophagus showing the usual point of impaction.

Odynophagia may or may not be present, while dysphagia depends largely upon whether the foreign body causes partial or complete obstruction, whether it has caused or is causing injury to the mucosa or to adjoining laryngeal structures. Dyspnœa results if the foreign body is large enough to cause pressure on the trachea.

Before carrying out an œsophageal examination the buccal cavity, the lower pharynx, the upper orifice of the hypopharynx, and the larynx should be carefully inspected. In order successfully to perform an œsophagoscopy the patient should lie recumbent on the table with head slightly elevated and extended at the occipito-atloid joint. In this way the cervical portion of the spine is brought into line with the pharyngeal and buccal cavities. In young children no anæsthetic, local or general, is required. In adults, however, most operators prefer to have a general anæsthetic administered, although some, more especially our American confrères, are content merely to swab the pharyngeal mucosa with a 5–10 per cent. solution of cocaine. In young children no examination should be prolonged beyond 15 to 20 minutes, in adults beyond three-quarters of an hour. It is better to make two or more examinations than one prolonged one. As the œsophagoscope is being slowly introduced every portion of the œsophageal lumen should be carefully scrutinised, special attention being paid to the posterior wall where flat foreign bodies are prone to lodge. If attention is not paid to this point the instrument may override the foreign body as the mucosa is pushed forwards. As the œsophagoscope is slowly withdrawn the walls should again be carefully examined. The presence of a foreign body may induce a certain degree of spasm which adds to the practical difficulties of its detection. Much ingenuity is required in selecting the proper type of instrument with which to seize and to withdraw it without injuring the soft and movable œsophageal walls. The suggestion made by Chevalier Jackson of seeing, if possible, a duplicate of the impacted foreign body is well worthy of note. Great care is necessary to avoid wounding the mucosa when an attempt is being made to extract sharp-pointed objects, such as dentures with metal clips, pieces of bone, safety-pins, &c. Dilating the œsophagus with a Hill's dilator is at times of assistance, as is also the rotation of the foreign body in order to secure that any sharp edge or projection is trailed from below upwards. After removal of the foreign body a reinspection of the œsophagus should be made and a second X ray photograph taken, as more than one foreign body may have been present.

In those rare, and to-day exceptional, cases where attempts to remove the foreign body per vias naturale have failed, the performance of an œsophagotom has to be considered. The operation, practicabl only, however, when the foreign body is lodged i the cervical œsophagus, is by no means free fro danger. With existing technique it should be possibl to remove by œsophagoscopy any foreign body whic has been swallowed and become impacted, notwithstanding the practical difficulties encountered.

## FOREIGN BODIES IN THE AIR PASSAGES.

The symptoms presented by a foreign body impacted in the air passages will naturally depend upon its exact location, whether in the laryngeal cavity, the trachea, a bronchus, or a bronchiole. If in the larynx there is, as a rule, some interference with respiration, cough, hoarseness, odynophagia, and occasionally hæmoptysis. The larger the foreign body the greater the amount of dyspnœa and distress. In severe obstruction cyanosis and asphyxiation may become so urgent as to call for an immediate tracheotomy.

If lodged in the trachea Chevalier Jackson has drawn attention to three symptoms which he regards as pathognomonic—viz., an "audible slap," a "palpatory thud," and an "asthmatoid wheeze." The "audible slap," best heard at the patient's open mouth, is due to the expiratory blast striking the foreign body in its passage outwards; the "palpatory thud" indicates the actual detection of air impinging against the foreign body by means of the fingers placed over the trachea; while the "asthmatoid wheeze" is heard as the air streams past a foreign body impacted in one of the larger bronchial tubes.

It is important to note that a foreign body not causing severe obstruction may, after the initial irritative symptoms have passed off, cause no urge symptoms of any sort for a varying period. Th constitutes what Jackson has described as "t symptomless interval." Owing to the larger lume of the right bronchus and to its axis being more line with the trachea than is that of the left bronchu which also is somewhat narrower, foreign bodies hav a greater tendency to become impacted in the forme and also to slip down into the deeper portion of th bronchial tree.

A foreign body which completely obstructs a bronchus causes atelectasis, drowned lung, and, if not removed, pulmonary abscess. In addition, the opposite lung becomes emphysematous (compensatory) owing to overwork. The non-entrance of air into the lung causes loss of movement of the chest wall on the affected side, an impaired percussion note, and decreased vocal fremitus. Moreover, the air in the pulmonary alveoli below the site of obstruction becomes gradually absorbed with a resulting lung collapse and consequent cardiac displacement. Where the bronchus is, however, only partially occluded the physical signs will vary with the degree and constancy of the obstruction. Râles, both coarse and fine, are heard over the lung beyond the point of obstruction, although most intense just around it, while the percussion note is impaired and the movement of the chest wall and diaphragm more limited than normal. In addition, there develops a state of emphysema on the affected side, an obstructive emphysema, due to the fact that a certain, although small, amount of air enters the lung but very little escapes, with the result that air under pressure is retained in the immediate area of obstruction. Consequently, breath sounds are more or less inaudible and râles are heard.

Organic foreign bodies—e.g., beans, seeds, India corn, &c.—if retained for any length of time, tend to swell and to cork the lumen of the bronchus completely. Eventually they undergo maceration, break up, and induce purulency. The Roentgen ray pictures also vary in cases of partial and complete obstruction. In the former the obstructed side is more transparent, the diaphragm is depressed, and its movement is limited; in the latter the area of obstruction appears dense.

In the event of the foreign body being retained and causing suppuration, an abscess of the lung, bronchiectasis, or gangrene may result. An exact definition of the invaded area, lung-mapping, may be obtained either by the insufflation of carbonate of bismuth or the injection of lipiodol. The insufflation of bismuth is effected by passing a long insufflation tube down the trachea and blowing the powder with the aid of a pneumatic pump along the bronchus of the affected side. If a solution of lipiodol is preferred, about 30 c.cm. is injected by means of a long syringe passed well beyond the vocal cords. The fluid is moved as may be desired by altering the position of the patient and the outlines of any bronchiectatic cavity are thus delineated. In this way it is possible graphically to determine fairly accurately the position, size, and relations of any particular cavity, a matter of the greatest practical importance should the performance of thoracoplasty be contemplated.

Pneumonography, or "lung-mapping," as an aid to the detection of pulmonary suppuration, whether the result of retention of a foreign body or aspiration of septic material consequent to one or other operative procedure in connexion with the upper respiratory tract, has opened up a new and important field of clinical work.

The presence of sepsis demands drainage, and the difficulties of securing an efficient outlet vary with the location of the collection. So far as pulmonary suppuration is concerned, drainage may be secured as the result of an external operation, or by means of aspiration and lavage of the infected cavity through a bronchoscopic tube. An external operation is always attended by grave risk, while bronchoscopic evacuation of the abscess cavity in suitably selected cases is practically free from danger.

Not only may the cavity be freed from its purulent contents by aspiration, but it may also be washed out with a suitable and non-irritating solution, such as that recommended by Moore and Lukens—viz., trinitrophenol gr. ii., Lugol's solution 1 drachm, and normal saline solution 1 pint. The injection is made without any anæsthetic, local or general, once a week or even oftener, care being taken to treat only small areas at each sitting and to avoid flooding healthy lung tissue.

The coöperation of the physician, the surgeon, the radiologist, and the bronchoscopist is essential if the best results are to be obtained. Much thought and consideration are necessary before any actual attempt to remove a foreign body from a bronchus is made, its exact localisation and the proper type of forceps for its removal being of the utmost moment, as rapidity of action is a matter of importance to the patient.

---

# An Address

ON THE

# FAILED FORCEPS CASE.

*A Post-graduate Lecture delivered at Queen Charlotte's Hospital and at a Meeting of the South-West London Post-graduate Association*

BY LEONARD PHILLIPS, M.S., M.B.,
B.SC. LOND., F.R.C.S. ENG.,
SURGEON TO IN-PATIENTS, QUEEN CHARLOTTE'S MATERNITY HOSPITAL; SURGEON TO OUT-PATIENTS, THE HOSPITAL FOR WOMEN, SOHO; OBSTETRIC TUTOR, ST. MARY'S HOSPITAL, PADDINGTON, W.

IT frequently happens that forceps fail to effect delivery, either because they slip or because no progress is made in spite of strong traction. In these cases it is important to re-examine the patient, and review carefully the whole situation rather than persist in ineffectual attempts at delivery which injure the mother and sacrifice the child. In this examination special attention should be paid to the following points.

1. *General Condition of the Patient.*—The time which has elapsed since rupture of the membranes; the presence of a rising pulse or temperature.

2. *Abdominal Examination.*—(*a*) Do the pelvic measurements suggest flattening or general contraction, or are they normal? If pelvic contraction is present, does it allow extraction of a dead perforated baby, or must a Caesarean section be done. (Internal conjugate less than 3 in., transverse at the brim less than 3½ in.) (*b*) The position of the head in relation to the brim—i.e., is it above, in, or through the brim. The head above the brim can be moved from one iliac fossa to the other. An engaging head has a much narrower lateral excursion, while an engaged head is immobile and grasped with difficulty. When the head has passed the brim there is complete disappearance of the cephalic prominence on abdominal examination. Forceps should not be applied to a floating head, and the higher the head is found to be in the pelvis the more carefully should the indication for their application be considered. (*c*) The condition of the lower segment. The uterus may be tender, especially in the lower segment, and closely moulded to the child. There is great risk to the mother if internal manipulations (especially internal version) are carried out in such circumstances. (*d*) The condition of the child. Can the fœtal heart be heard? If the child is alive, can it be reasonably expected to live even if delivered without further trauma? (*e*) The position of the occiput. The position of the back, fœtal heart sounds and limbs, as a guide to the possible existence of a persistent occipito-posterior.

3. *Vaginal Examination.*—(*a*) The presence or absence of lacerations, bruising, and œdema of the perineum, vulva, and vagina. (*b*) When the head is in the cavity, the position of the occiput, as determined by passing the whole hand into the vagina, and the presence or absence of a contraction ring round the child's neck. (*c*) The possible existence of a tumour in the pelvis, bulging forwards the posterior vaginal wall and preventing descent of the head.

The *Common Causes of failed forceps are:* (1) Unrotated or partially rotated occipito-posterior positions of the vertex; (2) a contraction ring round the neck of the child; (3) pelvic tumours; (4) a contracted pelvis: head at the brim, flat pelvis; head in the cavity, generally contracted pelvis. The investigation outlined above not only permits the diagnosis (1) to (4) to be made, but supplies the data which determine the different alternative treatments.

## "OCCIPITO-POSTERIOR" CASES.

Third and fourth vertex positions frequently cause much trouble in labour, and when the forceps are applied in cases of absent or incomplete rotation slipping usually occurs. If the occiput is directed towards one or other sacro-iliac joint, one blade of the forceps comes to rest over the anterior eye, the other blade behind the opposite ear. Slipping is the natural result. The first forceps delivery seen by the writer was in such a case and resulted in evulsion of one eye, and the baby was born alive. When the occiput has incompletely rotated forwards so that it faces the side wall of the pelvis, the grip of the blades is again bad, one being over the occiput and the other over the forehead, and slipping is likely to occur. Moreover forceps traction in such cases is an attempt to pull the occipito-frontal diameter of 4½ in. through the transverse diameter of the pelvic outlet, which is only 4 in. In such cases forward manual rotation of the occiput one-quarter of a circle allows the blades a correct grip and results in an easy extraction as the presenting diameter is then in the widest diameter of the outlet—the antero-posterior of 4½ in.

If the occiput has rotated backwards into the hollow of the sacrum, a good grip may be obtained with the forceps and strong traction may effect delivery, but practically always at the expense of the posterior vaginal wall and perineum, the latter being frequently torn into the rectum. The consultant is frequently asked whether induction of premature labour should be performed in a particular case, because the last labour was a difficult forceps delivery and ended in a badly torn perineum and an asphyxiated baby. Often in such cases the pelvis is found to be normal in size, and there is no obvious cause for the former difficult labour. The explanation is often an unrecognised occipito-posterior vertex delivered face to pubes. In the next labour the baby may arrive before the doctor. Again he is sometimes asked to perforate because prolonged traction fails to deliver the baby, though the head is almost on the perineum; yet in such cases forward rotation of the occiput one-quarter of a circle, for the reasons already given, often allows an easy extraction of a living child. If the doctor has already told the relatives that the child is dead and must be perforated, the extraction of a living child may create an awkward situation.

Failure to recognise a case of backward rotation, non-rotation, or incomplete rotation in a third or fourth vertex—with the results given—is very easily understood. The delay is thought to be the result of disproportion between the head and the pelvis. This it is, but it is a disproportion due entirely to the position and not to the size of the head. The latter is descending midway between flexion and extension, and the occipito-frontal diameter of 4¾ in. (circumference 14 in.) is distending the vagina, whereas in the well-flexed vertex which develops in first and second positions, the descending diameter is the sub-occipito bregmatic of 3¾ in. (circumference 12 in.).

If (as so often happens) the membranes rupture early and the uterus becomes closely applied to the child, or if the patient is very fat or nervous, the practitioner may not make out satisfactorily the position of the back, limbs, and fœtal heart. Later, on vaginal examination, a large caput may obscure or render difficult the palpation of sutures and fontanelles, so that when delay in the second stage occurs, in spite of strong pains and a head low in the pelvis, the diagnosis of moderate disproportion is made and consequently the forceps applied. The slipping of the blades, the abnormal length of the perineum, and the commencing rupture of the latter before even the vulva is distended by the head should provide ample warning in time to correct the diagnosis, rotate the occiput forwards, and so prevent a catastrophe.

In all such cases, after removal of the blades, it is wise to pass the whole hand into the vagina and over the fœtal head until the face or neck are reached, locating exactly the position of the occiput. Then, when the head is pushed up sufficiently to allow it to be grasped and to disengage the anterior shoulder from the pelvic brim, the back of the child should be pushed over to the opposite side of the uterus by the hand manipulating the abdomen, while the other hand in the vagina rotates the occiput to the front. If rotation of the shoulder and back is successfully accomplished the occiput remains in its forward position and the re-application of the forceps and the extraction are usually easy. Occasionally it is impossible to push up, rotate, or pull out the head. In these cases, fortunately not common, the forceps can be left on, and the perforator passed between the blades, after which extraction may be possible without recourse to the cranioclast.

### CONTRACTION RING.

Exactly why the uterine muscle should develop a condition of local spasm we do not know, but such a contraction ring round the child's neck probably causes failure in forceps delivery more often than we suspect. The circumstances, however, are so typical that the cause can usually be suspected at once. The practitioner, in fact, is usually sorely puzzled because he cannot deliver, and yet can find no obvious explanation. The condition of the patient is usually good, the pelvic measurements may be normal, the head not unduly large, even in the pelvic cavity. There is no pelvic tumour. Even the occiput is anterior and the forceps are applied easily and grip well; yet the head cannot be extracted and the little advantage gained by traction is lost when the pull is discontinued. There is usually a history of early rupture of the membranes, and a rather protracted labour with many examinations and possibly some obstetric manipulation. The diagnosis can only be made with certainty by introducing the whole hand into the vagina and feeling the tight ring of muscle round the child.

*Treatment.*—The natural temptation to stretch the ring with the fingers should never be indulged, as it invariably increases the spasm. Early cases in which the child is alive should be treated by repeated small doses of morphia. Then after 12 to 24 hours, if the patient is deeply anæsthetised, delivery by forceps can usually be effected.

In late cases the child is dead and Cæsarean section is contra-indicated unless other procedures, less dangerous to the mother, fail. The head should be perforated and the cranioclast applied, a weight of 7 lb. being attached to the handle and left hanging over the bed. Steady weight traction usually succeeds in the end, but the writer can recollect one case in which it failed, and on opening the abdomen the ring round the child's neck was so tight that it appeared quite anæmic, and required incision before the mother could be delivered.

### PELVIC TUMOURS.

Pelvic tumours complicating labour are not common, but when present they are often overlooked, with the result that attempts are made to drag the child past a fibroid or ovarian cyst, with serious consequences. Fibroids, unless cervical, rarely prevent the head from descending. Even lower segment fibroids, unless large and low down, usually undergo softening and flattening, and, as labour advances, are drawn up out of the way. Ovarian cysts, especially dermoids about the size of an orange or less, lie in Douglas's pouch, symptomless and unsuspected for years until pregnancy or labour lead to their discovery.

*Treatment.*—Forceps, version, and craniotomy play no part in the treatment of tumours complicating labour. No attempt should ever be made to drag a child past a fibroid or ovarian cyst, either by its feet or its head, before or after perforation. Such attempts are fraught with great danger to the mother, and, apart from the effect on the tumour, are likely to produce serious injuries to the genital canal. Injured fibroids frequently become infected in the puerperium, and infected fibroids are very deadly. Most of the deaths in cases of fibroids complicating childbirth are the result of infection of these tumours after delivery. In the same way an ovarian cyst is likely to rupture if a child is dragged past it. The contents of the cyst escape into the peritoneal cavity, the result depending on the nature of the cyst. The difficulties of the ovariotomy, which must subsequently be performed, are considerably increased by the occurrence of this accident. When the obstructing tumour is a fibroid Cæsarean section should be performed, either alone or followed by myomectomy or hysterectomy, according to the indications for each. If the tumour is ovarian it is better to avoid incision of the uterus, if possible. Cæsarean section exposes these patients to the very definite risk of rupture of the scar in subsequent natural labours, or to the alternative risk of repeated Cæsarean sections. If interference is delayed until the os is fully, or nearly fully, dilated, the ovarian cyst can be removed after opening the abdomen, an assistant delivering with forceps before the abdominal wound is closed. If the tumour cannot be removed, even after eventrating the uterus, the latter may require incision before the cyst can be withdrawn from the pelvis, where it is imprisoned by the head pressing the pedicle against the promontory or lateral pelvic wall; but it is always better to avoid Cæsarean section if possible.

### DISPROPORTION BETWEEN THE HEAD AND THE PELVIS.

The first essential in these cases is to decide whether the pelvis is too small to allow extraction of a craniotomised child without great risk to the mother. At Queen Charlotte's Hospital an internal conjugate of less than 3 in. and a transverse diameter at the brim of less than 3½ in. are considered the minimum measurements which allow delivery of a destroyed child without great risk to the mother. In such cases Cæsarean section with or without hysterectomy is the only rational treatment. With measurements greater than these there are four possible alternatives after failure of the forceps to effect delivery: (1) pubiotomy; (2) internal version; (3) Cæsarean section; (4) craniotomy.

*Pubiotomy.*—This operation is very rarely performed by English obstetricians, and has given such disappointing results in this country that it has been abandoned and can be said to play no part in our practice of midwifery. Continental and American writers have published series of cases with good results. The operation is essentially one for the expert. There is a definite risk of injury to the bladder and soft parts, it amounts to the production of a compound fracture in a presumably septic area, and it is an operation thoroughly unsuitable for recommendation in general practice.

*Version.*—Internal version, on the other hand, is a practical and popular obstetric procedure, though of somewhat limited application.

It is likely to prove successful if the following conditions obtain: 1. An internal conjugate of not less than 3¼ in. with an average-sized head. 2. A flaccid uterus not thinned or moulded to the child, so allowing version to be performed without risk of rupture of the uterus. 3. The head above the pelvic brim, or if in the brim able to be pushed up without undue application of force. 4. It is especially of value in cases of unfavourable vertex presentation at the brim—i.e., a brow, or a posterior parietal presentation in which the anterior parietal bone overlaps the symphysis and the sagittal suture remains near the symphysis pubis. In such cases it is more than likely that internal version will cause to engage in the pelvic brim a smaller and more favourable diameter of the after-coming head.

After bringing down the arms the anterior shoulder should be kept under the symphysis and the head pushed through the brim by strong fundal pressure. This promotes a certain degree of flexion and ensures the long diameter of the fœtal head (the occipito frontal of 4½) engaging in and passing through the longest diameter of the brim (the transverse of 5 in.) while the narrowest transverse diameter of the head (the bi temporal of 3¼ in.) passes through the narrowest diameter of the brim—i.e., the internal conjugate, the wider bi parietal diameter being in the roomy lateral part of the pelvis. When the head has passed the brim the child is rotated so as to bring the nape of the neck under the symphysis and the head is then easily delivered by jaw and shoulder traction. It should be remembered that extraction as a breech has many disadvantages both for the mother and the child, especially the risk of injury and asphyxia of the child, and the likelihood of a severe rupture of the perineum in bringing down the arms, but it has one very great advantage—namely, that should it be impossible to push the after-coming head through the brim, perforation and extraction of the head in this position is an easier and safer operation than perforation and extraction of a fore-coming head floating above the brim.

*Internal Version with the Head in the Cavity.*

When forceps fail to deliver a head in the pelvic cavity, it is doubtful whether any advantage is to be gained by version, while in many cases in which the head cannot be pushed up easily the practice is fraught with considerable danger, especially the risk of rupture of the uterus, the uterus being pushed off the vagina. In the absence of general contraction, it is often of greater advantage to rotate the head into a larger and more favourable diameter for extraction, and then to re-apply the forceps, when delivery will often follow. If the pelvis is generally contracted, especially in the funnel-shaped masculine type of pelvis, internal version is a distinct disadvantage. Here the pelvic diameters diminish from above downwards and strong pains drive the head into the funnel, promoting strong flexion, which is increased by traction with forceps. On the other hand, the descent of the after-coming head through such a pelvis is certain to result in extension of the head and elevation of the chin. If the perfectly flexed fore-coming head cannot be extracted by strong forceps traction, how much more unlikely of success is the extraction of the extended after-coming head.

### CÆSAREAN SECTION AND PERFORATION.

In extreme degrees of pelvic contraction Cæsarean section is the only rational treatment, irrespective of the duration of labour. Similarly in moderate degrees of contraction when the child is dead, perforation is recognised as the correct treatment if forceps fail and version is contra indicated.

But in cases of *moderate* contraction, in which forceps have failed and the child is still alive, there is a choice between Cæsarean section and perforation of the living child. There is a growing tendency to extend the scope of Cæsarean section to these cases, irrespective of the greatly added risk to the mother. Indeed, one is frequently asked nowadays whether it is ever justifiable to sacrifice a living child. This question can only be answered after comparing the maternal mortality and morbidity rates of Cæsarean section and craniotomy.

The operation of Cæsarean section performed before rupture of the membranes, in ideal surroundings with a strict surgical aseptic technique and by surgeons accustomed to abdominal operations, is such a safe operation, so simple to perform, and gives such excellent results, that there is an increasing danger of the operation being extended to unsuitable cases, after rupture of the membranes, where the surroundings are not ideal and the best technique is not obtainable. In these cases the results are extremely bad. Amand Routh's series of analysed cases deals with the Cæsarean sections in this country from 1891–1910, while Holland and Kerr's collected cases (over 1000 in number) analyse the Cæsarean sections performed in the leading hospitals of the British Isles from 1911–20. In Routh's[4] series the maternal mortality in cases operated upon before rupture of the membranes was 2.0 per cent., while in cases operated upon after rupture of the membranes it was 10.8–31.3 per cent., the higher figure of 31.3 per cent. corresponding to those cases in which many examinations or attempts at delivery had been made. In Holland and Kerr's[5] series the maternal mortality was 1.6 per cent. in cases of operation before rupture of the membranes, and 10.27 per cent. in cases after rupture of the membranes; again, the higher figure referring to later cases in which forceps had been attempted and in which bruising, œdema, and laceration of the genital canal were stated or assumed to be present.

These figures, representing as they do the collective results of the most experienced surgeons in the British Isles working in large hospitals and under ideal conditions, must, of necessity, carry tremendous weight, and should exercise a real influence on teaching and practice in regard to this operation. The figures show: (1) That in cases of operation at the time of election there is a definite mortality-rate between 1·5 and 2 per cent.—a small but a definite and probably an irreducible minimum rate. (2) That Cæsarean section performed late in labour has a minimum mortality of 10 per cent. and a maximum of 27 per cent. under the *best* available conditions. These deaths are chiefly from septic complications: peritonitis, septicæmia, pyæmia, pulmonary embolism, &c. In addition there is a heavy morbidity-rate in surviving patients due to chronic pain from adhesions, intestinal obstruction from adhesion of small intestine to the uterine stitch line, white leg, utero-abdominal fistulæ (through which menstrual fluid may escape), and many other conditions.

The enthusiasts for Cæsarean section reply that the results of craniotomy are equally bad. *This is not true*, and the mortality from this operation would be even less if obstetricians took the pains to perfect themselves in a truly obstetric procedure rather than give way to the temptation to perform a more showy operation irrespective of the greatly added risks to the mother. In 100 cases of craniotomy at Queen Charlotte's Hospital analysed by the author there were only eight deaths, and it must be remembered that most of these perforations were in grave cases, sent in from surrounding districts, after ineffectual attempts at delivery, cases in which œdema, bruising, and laceration of the genital canal were present, and sometimes even established infection with ante-partum pyrexia and discharge. In these cases the mortality of Cæsarean section is not 8 per cent. but 27 per cent. In Shauta's[2] analysis of 50,000 labours, with nearly 5000 cases of contracted pelvis, there were 82 craniotomies on dead babies with only five deaths—i.e., 6 per cent.—and 76 craniotomies on living children with only one death—i.e., 1·3 per cent.—the lower figure in the latter series being readily understood, as the factors which predispose to septic complications are less likely to be present when the child is alive and less damage has been done to the mother.

It is sometimes stated that the risks of sepsis in late cases of Cæsarean section are exaggerated, but it is unreasonable to disregard figures such as those here quoted, and especially in regard to this matter does a grave responsibility rest upon the shoulders of teachers of obstetrics. If, therefore, in a case of moderate disproportion some error of judgment has been made, which results in failure of forceps to effect delivery, is it not incumbent upon the practitioner to perforate the living child rather than subject the mother to a death risk of 10–27 per cent? Even if the fœtal heart is still audible the child cannot be reasonably expected to live in a great many cases after a long and steady pull with forceps. The attitude of the husband in these cases is the correct one. "Save my wife, never mind the baby," is the universal reply *if an unprejudiced case is presented to him*. He, at any rate, is able to estimate correctly the relative values of the two lives.

Sir George Blacker[1] states that

> the majority of obstetricians of experience hold strongly to the view that it is rarely if ever justifiable to subject the mother to a grave risk in order to save the life of a child. Naturally it is a very repugnant action to have to perforate a living child, but to pretend that craniotomy can be replaced by symphysiotomy or Cæsarean section without much greater danger to the mother is to shut one's eyes to the truth.

In most of these cases the mother is young and when she conceives again can have induction of labour at about the 36th week (maternal mortality-rate 0·2 per cent.) or Cæsarean section just before term (maternal mortality 1·6 per cent.). Every obstetrician of experience has had cases in which cranioclasm has been followed in a subsequent pregnancy by induction of labour or Cæsarean section with little risk and excellent results. It is sometimes maintained that modifications in the technique of Cæsarean section may, or do, greatly diminish the maternal mortality in operations performed late in labour. But it has not yet been proved that there is sufficient reduction in that rate to justify substitution of these operations for craniotomy. Both the extra-peritoneal operation and incision of the lower segment are more difficult to perform, there is more risk of injury to the bladder, and infection of the uterine incision in the lower segment operation would seem more likely.

Cæsarean hysterectomy is an operation with a high mortality rate, and it cannot be usually justifiable to perform an operation of this character on a young woman for the sake of a very doubtful fœtal life, when the sacrifice of that baby will enable her to retain the uterus and bear children in the future under better circumstances with much less risk. The degree of infection in cases considered suitable for Cæsarean hysterectomy is always doubtful, and the majority of the mild cases of uterine infection recover if the child is extracted per vaginam. Bar's[3] eventration operation is probably the most promising of these modified operations and, in my own cases up to the present, has given a mortality of only 5 per cent.

The important distinguishing details of the operation are as follows. The abdominal incision is made long enough to enable the uterus containing the child to be eventrated. The edges of the wound are temporarily clipped together as far as possible behind the uterus, and sterile towels placed between the uterus and the abdominal wound, so as to completely exclude the peritoneal cavity from the area of operation. The uterus is then incised and the child removed. The placenta and membranes are peeled off, and large swabs or rolls of gauze half wrung out in 1 per cent. violet green, 1-1000 flavine, or strong milton, are placed in the uterus, and the latter is tightly squeezed around them for several minutes thus attempting to sterilise the newly created raw surface made by removal of the placenta and membranes. The gauze is then removed and the uterine incision closed and the outer surface of the uterus washed over with violet green or flavine. Then the towels around and behind the uterus are removed, a new gown and gloves are put on, a fresh set of instruments is taken, and fresh sterile towels are placed over the abdomen and around the abdominal wound. The uterus is then replaced in the abdominal cavity and the abdomen closed in layers. In this way contamination of the peritoneal cavity is prevented as no uterine contents escape into it, and also a definite attempt is made to render the interior of the uterus sterile.

In presumably infected cases the operation gives very good results, but a sufficient number of cases has not yet been published to justify the extended use of the operation as an alternative to craniotomy, though it is probably the best of the modified methods of Cæsarean section for septic cases.

With regard to the technique of cranioclasm itself there are a few important points in technique which make for success and which are not usually emphasised. After perforating the skull it is important to break up the septa at the base of the brain, so as to allow the solid blade to be passed right down to the medulla. This blade should be passed with the rough surface towards the face. The hollow blade is then passed right over the face, and if the solid blade has been passed down to the medulla, locking will be effected with the hollow blade over the face, a good grip is obtained on screwing up the handles, and an easy extraction by traction alone follows. It is rarely necessary to remove separately the bones of the vault. If the solid blade is not pushed well home, locking is secured with the hollow blade over the forehead and not the face. On tightening the screws only the frontal bones and scalp are included between the blades and slipping is inevitable. The three-bladed cranioclast, though not in common use, has a great advantage over the two-bladed instrument in difficult cases and is invariably used at Queen Charlotte's Hospital.

### PREVENTION OF FAILED FORCEPS AND DIFFICULT FORCEPS.

*Induction of Labour and Trial Labour.*—Difficult and unsuccessful forceps deliveries are usually preventable by antenatal supervision, ending in induction of labour at some time between the 30th and 38th week of gestation. From 1908–17 434 cases were induced at Queen Charlotte's Hospital. There was only one maternal death (0·23 per cent.), and 340 of these were delivered spontaneously with a fœtal and neonatal mortality of 37 (10·8 per cent.). *Ninety-four were delivered by forceps with a mortality of 17 per cent.* The following table shows the cases analysed.—

| Period of gestation. (weeks) | No of cases* | Fœtal and neonatal deaths | Percentage | Period of gestation. (weeks) | No. of cases.* | Fœtal and neonatal deaths | Percentage |
|---|---|---|---|---|---|---|---|
| 40 | 120 | 19 | 15·8 | 34 | 12 | 5 | 41·6 |
| 39 | 52 | 6 | 11·5 | 32 | 4 | 2 | 50·0 |
| 38 | 122 | 8 | 6·8 | 30 | 2 | 0 | — |
| 37 | 47 | 5 | 10·0 | 28 | 1 | 0 | — |
| 36 | 59 | 9 | 15·3 | 24 | 1 | 1 | 100·0 |
| 35 | 4 | 2 | 50·0 | | | | |

* In the last five years over 100 inductions per year have been carried out at Queen Charlotte's Hospital.[6]

The fœtal and neonatal mortality for the whole series was 13·3 per cent. For the cases from 36–40 weeks it was 11·7 per cent. The higher mortality during the 39th and 40th weeks was probably due to some of these cases being left a little too long. The *table shows the high mortality* of induction before the 36th week, and the great value of this operation from the 36th–38th week. The majority of the cases of contracted pelvis encountered in the South of England are of the moderate kind, rarely needing Cæsarean section, but frequently ending in difficult forceps and death of the child, and sometimes in failed forceps and perforation. It is just this type of case which is so amenable to treatment by induction between the 36th and 38th week. Earlier than the 36th week the children *usually* weigh under 5 lb. They are reared with difficulty and often fail to stand the stress of labour. If in a case of disproportion examined at or before the 36th week the head *cannot* be pushed into the brim, Cæsarean section at term is indicated. If *the head at the 36th week can just be* pushed into the brim with great difficulty, induction of labour should be performed within a few days. If at the 36th week the head pushes in easily, weekly repetitions of the test should be carried out, induction being performed when the head can just be pushed in with difficulty; the case never being allowed to pass beyond the 40th week. If a patient is to be seen once only in the antenatal period, let it be *in the 36th week.* These principles in estimating the time for induction are followed religiously at Queen Charlotte's Hospital, where the medical staff is convinced of their great value in the prevention of difficult forceps deliveries, stillbirths, and perforations in labour.

*The Trial Labour.*—The difficult cases are those seen for the first time at or near term, in which the obstetrician cannot be sure whether the head will pass through the brim, even after repetition of the test under anæsthesia. Although midwifery is an exact science, the human element involved in matters of judgment renders inevitable *occasional mistakes,* so that the most experienced accoucheur may be ultimately faced with a difficult forceps or a perforation, in spite of antenatal supervision. It is in these doubtful cases that trial labour has such a great value; not a trial of nature *à outrance,* where *perforation* is permissible in the end, and the *trial* is for future guidance—i.e., our conduct in the next labour—but a trial of spontaneous labour against Cæsarean section, a trial in which perforation is a mark of failure, and even forceps is avoided if possible.

In such a case the decision must be made as early as possible after rupture of the *membranes,* because the risks of Cæsarean section increase rapidly after that event. Valuable information can be obtained by *repeated abdominal examinations of the head at the* pelvic brim as labour advances. In favourable cases flexion and fixation of the head in the brim are followed by disappearance of the overlap at the symphysis pubis, and *finally by inability to feel the cephalic prominence* per abdomen. When these signs occur in succession, the case can be left alone and at most will need a medium or easy low forceps. In unfavourable cases the membranes rupture early, the cervix dilates *slowly, the pains are weak,* and descent, fixation, and disappearance of the overlap fail to occur or are delayed too long. Sometimes prolapse of the cord occurs, making an immediate decision necessary.

If Cæsarean section is performed in such a trial labour where an aseptic technique has been followed, few vaginal examinations and no attempts at delivery made, and in which bruising, œdema, and laceration *of the genital canal are absent, the risk of the operation* is little greater than that at the time of election. It is best to exclude high forceps entirely from such a trial labour, but should the practitioner be tempted to apply them, the head being jammed in the brim and *the os fully dilated, great care* should be taken to *apply them carefully and to pull tentatively* and steadily for not more than 15 minutes. Then if no marked progress has been made, it is wiser to remove the forceps without injury to the genital canal and to consider the question of Cæsarean section before it is too late. At such a stage the baby might be reasonably expected to live, and the risks of Cæsarean section, though definite, are not prohibitive, but *if, as so often* happens, anæsthetist and accoucheur exchange tasks, *and repeated prolonged and unsuccessful attempts at* forceps delivery are made, the child's life is a poor risk, the genital canal is bruised, lacerated, and possibly definitely infected, and the *risks of Cæsarean section* to the mother are so great as to contra-indicate entirely that operation.

# THE DIFFERENTIATION OF FOOD-POISONING BACTERIA.

BY H. C. BROWN, C.I.E., M.B., *B.CH. CAMB.,*
MAJOR, I.M.S. (RETD.), WELLCOME BUREAU OF SCIENTIFIC RESEARCH,

J. T. DUNCAN, F.R.C.S.I., D.T.M. & H. CAMB.,
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE,

AND

T. A. HENRY, D.SC. LOND.,
DIRECTOR, WELLCOME CHEMICAL RESEARCH LABORATORIES.

DURING the last few years considerable attention has been directed to the causation of outbreaks of food poisoning. Apart from those due *to B. botulinus,* others caused by members of the Salmonella group occur from time to time. Burgess[1] has recently described an extensive outbreak of 703 known *cases due to B. aertrycke.* Of recent years, apart from the work of Andrewes,[2 3] Schutze,[4 5] Topley,[6] and that of Savage and Bruce-White,[7] all of which deals essen*tially with the serological* aspect of the subject, not much has been added to our knowledge which will help the worker in smaller laboratories to differentiate the members of this perplexing group of organisms. Savage[8] refers to these organisms as being nearly *indistinguishable culturally and* morphologically from one another, and says that they constitute a kind of no-man's land which needs exploration urgently. He further says: "I feel that *much* value to public health and epidemiology would accrue if this neglected field was more thoroughly surveyed."

### *Failure of Sugars to Differentiate.*

Now when the worker in the smaller laboratories is faced with an investigation into one of these outbreaks it is essential for him to be certain that the abnormal flora in the patient's dejecta are identical with those in the articles of food causing the outbreak. If he is in possession of mono-specific sera advocated by Andrewes[3] he will have no difficulty in proving the identity of organisms from these two sources, but if he does not happen to have these sera he will have to rely on cultural characteristics. Here the "sugars" will help him, but only up to a certain point, and even with the rarer compounds, such as inositol, he will not be able to differentiate many members of the Salmonella group.

It is where the "sugars" fall short in this differentiation that we would urge the employment of certain organic salts for this purpose. It has been shown that with the "sugars" the Salmonellas (*B. paratyphosus* A included) can be differentiated into four groups, and that by the study of the fermentation of certain organic salts[9] seven groupings can be obtained, and by means of both sugars and organic salt reactions a total of eight groupings is possible.

### *The Help of Salts of Organic Acids.*

The salts which we have found most useful in differentiating the Salmonellas are: the sodium salts of citric, *d*-tartaric, *l*-tartaric, *m*-tartaric, fumaric, and mucic acids. These are employed in a peptone water medium in a concentration of 1 per cent., and they are not materially affected by sterilisation in the autoclave. The cultures in the salt media are incubated at 37° C. for 48 hours, and decomposition of the salt is then investigated by adding a sufficient quantity of a soluble lead salt; 0·6 c.cm. of a saturated solution of lead acetate to every 5·0 c.cm. of the tartrate medium, or 0·5 c.cm. to a similar quantity of the citrate medium. All of the acids mentioned yield insoluble lead salts, and, with the exception of fumaric and mucic acids, the precipitate caused by the addition of lead acetate is bulky and tends to remain in suspension, forming a white flocculent column. Decomposition of the salt is evidenced, on adding the precipitant, by the formation of a slight granular greyish-white precipitate composed chiefly of lead carbonate, which sinks rapidly to the bottom of the tube.

In the case of fumaric acid the lead salt forms a slight heavy precipitate, quite unlike the light voluminous precipitates given by the other acids. Sodium fumarate, however, is very readily acted upon by all members of the Salmonella group, and the earliest results of this action are the formation of small quantities of sodium carbonate and sodium succinate, in the presence of either or of both of which lead fumarate forms a bulky precipitate like that of lead citrate or tartrate. *B. paratyphosus* A and *B. paratyphosus* C do not carry the decomposition of fumarate beyond this stage, but all the other Salmonellas complete the decomposition of the fumarate and succinate, leaving only a residue of carbonate. It has been found desirable to extend the incubation period to 96 hours, in the case of this salt, in order to allow for its slower decomposition.

In the case of mucic acid, precipitation by lead also yields a small heavy precipitate which, however, may readily be distinguished from the lead carbonate, in the tubes in which decomposition of the salt has occurred, by adding a little acetic acid, which will dissolve lead carbonate but not lead mucate.

### *Results up to Date.*

For a more detailed account of the technique of these tests, the reader is referred to our previous paper.[9] Since this paper was published we have had the opportunity, thanks to the kindness of Mr. Bruce-White, of further studying the action of eight more strains of bacteria, all isolated from cases of food poisoning on the organic salts. In the case of each organism the result of the action on the organic salts was directly correlated with the serological findings obtained by Mr. Bruce-White, and it is interesting to note that three strains of the newly described Derby type and the single strain Dar-es-Salaam stand out from the other Salmonellas, both in their action on the organic salts and in their serum reactions. Altogether we have studied the action of a total of 78 strains of the various Salmonellas, and in every instance the nine groupings which we have arrived at have been clearly differentiated one from another.

The following table illustrates the actions of the various Salmonellas on the six salts selected. A − sign indicates that the salt is unaffected, and a + sign that complete decomposition has occurred.

| — | Citrate. | *d*-tartrate. | *l*-tartrate. | *m*-tartrate. | Fumarate. | Mucate. |
|---|---|---|---|---|---|---|
| *B. paratyphosus* A.. .. | − | − | − | − | − | − |
| *B. paratyphosus* B.. .. | + | − | + | − | − | + |
| *B. paratyphosus* C.. .. | + | + | − | + | − | − |
| *B. suipestifer* .. .. | + | + | − | + | + | − |
| Salmonella type "G" .. | + | + | − | + | + | − |
| Type Reading .. .. | + | + | − | + | + | − |
| Type Mutton .. .. | + | + | + | + | + | + |
| Type Newport .. .. | + | + | + | + | + | + |
| Type Binns .. .. | + | + | + | + | + | − |
| Type Stanley .. .. | + | + | + | − | + | + |
| Dar-es-Salaam, Bruce-White | + | − | − | − | + | + |
| Type Derby .. .. | + | + | + | + | − | − |
| *B. enteritidis* Gärtner .. | + | ± | ± | ± | + | − |

The only member of the Salmonella group which has given inconstant results with the organic salts is *B. enteritidis* Gärtner. Here, although the various strains have apparently been identical from a morphological and serological aspect, the activity with which they attacked the organic salts has been very irregular.

In our previous paper[9] we indicated the possibility of distinguishing *V. choleræ* from other vibrios by means of salt fermentations. This assumption was based on the results of tests carried out with the few strains of vibrios available at the time. On a more extended investigation, made possible through the kindness of Dr. R. St. John-Brooks, who supplied us with a large number of strains of *V. choleræ* and cholera-like vibrios, we have been unable to confirm our previous opinion; some of the cholera-like vibrios behaving like the true *V. choleræ* in their fermentations.

In conclusion we would urge the use of these salts of organic acids as offering the most valuable of the biochemical means of differentiating the various members of the important Salmonella group.

---

**RESIGNATION OF JOHANNESBURG M.O.H.**—The resignation of Dr. Charles Porter, medical officer of health for Johannesburg for 23 years, has produced warm tributes from the Pietermaritzburg Congress and in the South African press. After holding various public health appointments in England, including that of county medical officer for Shropshire, Dr. Porter went to Johannesburg under the régime of Lord Milner, and on the understanding that his appointment should be on the same terms of tenure as those obtaining in England. This proviso was the cause of adverse criticism, but allowed him to carry through the work he began. The *Rand Daily Mail*, in reviewing his achievements, draws attention to the fact that he came to the city at a time when nearly everything coming within the scope of a public health department in a well-ordered community had yet to be done, whilst he relinquishes office in the assurance that all those services are in a thoroughly satisfactory condition, and that Johannesburg is now one of the healthiest cities in the world. During the past 20 years the white death-rate has declined by 31 per cent. and the incidence of enteric by 87 per cent.

# AN ANALYSIS OF FOUR HUNDRED CONSECUTIVE CASES OF GONORRHŒA IN THE MALE.

### INVESTIGATED AND TREATED IN THE VENEREAL SECTION OF THE GENITO-URINARY DEPARTMENT OF THE LONDON HOSPITAL.

By E. R. TOWNLEY CLARKSON, M.R.C.S. ENG.,
SENIOR CLINICAL ASSISTANT, GENITO-URINARY DEPARTMENT (MALE), LONDON HOSPITAL;
AND
W. S. DYER,
REGISTRAR, VENEREAL SECTION (MALE) OF THE HOSPITAL.

THE present article deals with 400 consecutive cases of gonorrhœa in the male treated at the London Hospital Venereal Clinic. The authors hope that the following data and deductions may prove to be of interest and use from a clinical, administrative, and sociological standpoint. We must emphasise the fact that no attempt has been made in this clinic to achieve time records. We are conscious that in respect to the length of time taken to produce a cure our statistics will not compete with many other records, and we would here utter a note of protest against the increasing tendency to estimate results by an appeal to a mere numerical standard.

In this analysis, only those cases in which gonococci were found in the urethral film have been included.* Another feature which tends to reduce the number of cases considered is that only those patients who were officially discharged as cured enter into this calculation.

### *Routine Treatment.*

On the patient presenting himself for treatment the usual clinical history is taken—i.e., the date of exposure to infection, the date of onset of discharge, and enumeration of previous attacks. A urethral smear is then taken of which a microscopic and bacteriological examination is made. The anterior urethra is washed out with oxycyanide of mercury 1/5000, by Janet's method, and the patient is called upon to pass his urine. A rectal examination is made and the condition of the prostate and vesicles noted. The testes and epididymes are also palpated. The patient is urged to attend daily for irrigation and as required for prostatic and vesicular massage and urethroscopic examination and treatment. If he cannot come up for irrigation he is supplied with a syringe, with potassium permanganate solution of the requisite strength, and a leaflet with instructions and rules.

### *The Marriage Test.*

When all clinical symptoms have subsided, and an examination by the urethroscope has failed to reveal the presence of follicles or infiltrations, and a smear testifies to the normal condition of prostate and vesicles, then after all treatment has been suspended for one week the patient is subjected to the "marriage tests." These are carried out after one week has elapsed between the last treatment and the first test. They are three in number performed at weekly intervals (the patient meanwhile taking a little alcohol or receiving other provocative treatment).

Each marriage test involves a microscopic and bacteriological examination of urine and urinary deposit, a thread film and culture, a prostatico-vesicular film and culture, and vesicular contents per se when necessary. Only patients on whom three of these examinations have been made and have proved to be negative are passed as cured.

At first sight the number of patients remaining until formally discharged would seem disproportionately small—viz., 138 out of 400. But, owing to our proximity to the docks a substantial proportion of the patients are either seafaring men or engaged in casual labour at varying hours, for whom regular attendance during a number of weeks is impossible. Another class, largely represented in the clinic, is drawn from the alien population of the East End of London. Here again regular attendance at the clinic within specified hours on two days a week—when the clinic (apart from the irrigation department) is open—presents a difficulty which many patients fail to surmount. Hence their failure to attend for final tests, &c., when a cessation of signs and symptoms satisfies them that they are cured. It is obvious that a clinic in the densely populated area of East London cannot function as it should without being open on every day of the week.

### *Clinical Data as to Gonorrhœa.*

First attack, 294; second or more, 106.

*Proportion of Previous Attacks.*—It is a noticeable fact that of the 400 cases under consideration 106, or about one-fourth of the total number, had suffered from gonorrhœa on a previous occasion. When the fact is realised that most of the patients were under the age of 30, the proportions observed are even of greater interest, as showing that fear has no great power as a deterrent to exposure to infection.

### *Age of Patients.*

| Under 20 | 20–25 | 25–30 | 30–35. | Over 35. |
|---|---|---|---|---|
| 28 (7%) | 147 (36¾%) | 119 (29¾%) | 53 (13¼%) .. | 51 (12¾%) |

The conclusions arrived at after consideration of this table are: 1. That the years 20–25 appear to be the time of greatest danger. 2. That from 25–30 there is a marked reduction, to some extent due to marriage, possibly accounted for by increased prophylactic experience. 3. It is surprising that the percentage of patients under 20 years of age is so small, for it is in direct opposition to what one would expect. This figure must not be taken as forming an index of the extent of promiscuous intercourse which occurs under that age.

### *Influence of Alcohol.*

| Drunk. | | In liquor. | | Sober. |
|---|---|---|---|---|
| 51 (12¾%) | .. | 34 (8½%) | .... | 35 (78¾%) |

The attempt to correlate alcoholic indulgence with the incidence of venereal disease is extremely difficult. The terms "drunk," "in liquor," "sober" are extremely relative; some patients will advance "drunkenness" as an ethical excuse when no intoxication probably existed. Others, disliking the additional stigma of drunkenness, will deny a fact. If it were possible to obtain absolutely reliable data as to the condition of patients in respect to alcohol at the time of infection, valuable and suggestive results might be obtained as regards the correlation of alcohol to (*a*) the incubation period; (*b*) severity of the attack; (*c*) the extent of the time in terms of implication of the anterior and posterior urethra, and of the incidence of complications such as epididymitis, vesiculitis, and metastatic gonorrhœa.

### *Sources of Infection.*

| Prostitutes. | | Amateurs. | | Marital. |
|---|---|---|---|---|
| 252 (63%) | .... | 107 (26¾%) | .... | 41 (10¼%) |

In taking the clinical history the patient was always questioned as to the source of the infection; 41, or 10¼ per cent., denied conjugal incontinence, implying that the infection contracted was of marital origin; a card for the women's department was always given to be handed to the wife in these cases, and it is gratifying to report that most of the women came up to the department. 107, or 26¾ per cent., stated that they contracted gonorrhœa from women who were not prostitutes—i.e., women to whom no payment was made; 252, or 63 per cent., admitted associating with prostitutes. It will be noted that infection from prostitutes amounted to almost two-thirds of the total cases.

### *Incubation Period.*

| Days— | | | | | | | |
|---|---|---|---|---|---|---|---|
| 2 | 3 | 4 | 5 | 6 | 7 | 8 | over 8 |
| 52 (13%) | 69 (17¼%) | 57 (14¼%) | 52 (13%) | 37 (9¼%) | 56 (14%) | 14 (3½%) | 76 (19%) |

---

* See page 120, Gonococcal Rheumatism.

It will be seen that there is a wider difference in time in the incubation period than is usually described. Some cases show gonococcal pus in the urethra two days after the infecting coitus, others show no signs until after 14–21 days. The number in the last column is surprisingly high, 19 per cent., so that one is inclined to ask what are the factors which influence the incubation period? Is it the virulence of the organism or the resistance of the patient, or has the actual site of infection any causal relationship to time? Is it possible that there is a relationship between the species of gonococcus implicated and the length of incubation?

Gonococci grown on media in the laboratory under constant conditions do not show these wide variations in time; the inconstant but determining factor would seem to be associated with the patient. It is not the usual practice at the clinic to make urethroscopic examinations until at least three to four weeks have elapsed from the onset of disease. By that time the picture presented is one that gives no indication of the exact site of the entry of infection.

### *Cases of Anterior and Posterior Urethritis.*

The total number of cured cases of gonorrhœa were 138 out of 400. The cases which remained anterior—i.e., in which there was no infection of the posterior urethra, as shown by Janet's test and examination of the prostatic bead, and no infection of the vesicles—were 28, or 20 per cent. At first sight the proportion of cases which remained anterior seems low, but these results must not be compared with those that might be obtained in certain spheres of private practice where the patients can be placed in relatively ideal conditions, where they comport themselves with discretion, and carry out the precepts of their doctor with care. In a working-man's clinic, and especially in the neighbourhood of the docks, we find a large number of patients still carrying on heavy manual labour, which, apart from its effects upon the disease, also practically precludes the following out of the strict dietetic régime which is indicated. Their hours of work also prevent them from attending the irrigation room with regularity. Again, consideration has to be given to the question whether the marked indulgence in alcohol, particularly in spirits, which characterises many of the younger patients in this part of London, is not a factor in rendering the posterior urethra more susceptible to an extension of infection.

### *Cases of Epididymitis*

| First attack. | | | | Second or more. | | | |
|---|---|---|---|---|---|---|---|
| Right. | Left. | Both. | Total. | Right. | Left. | Both. | Total. |
| 20 | 23 | 1 | 44 | 11 | 7 | 2 | 20 |

Here we have to note that a very large percentage contracted epididymitis. Many of these cases, however, were already suffering from it when they appeared at the hospital. Of the remainder we must remember that many still continue to carry on their occupations, and those, at times, laborious ones, even when suffering from this complication. Apart from work, the factors of alcoholic indulgence, erotic excitement, and injudicious injections on the part of the patient will probably account for a large percentage.

Three points arise out of the consideration of the foregoing statements:—

1. There should be greater insistence on the necessity of patients immediately seeking adequate medical treatment after the onset of any urethral discharge.

2. That, in the opinion of one of us (E. C.), as soon as epididymitis of gonococcal origin is discovered, irrigations and injections should be reduced to the minimum required for comfort, and here Nature generally helps us by providing that there should be a marked reduction in the amount of discharge. It is better (with the foregoing proviso) that no irrigation should be given until the very acute stage of the epididymitis is passed. Markedly beneficial results have followed the adoption of this policy of abstention.

3. *Epididymitis, Efficiency and Economics.*—We are insistent that it is the duty of the community to provide far greater accommodation for the appropriate treatment of patients suffering from gonococcal epididymitis. In our own clinic we have three beds available for male patients suffering from gonorrhœa, a lamentably inadequate number. Time after time a patient suffering from epididymitis appears, his condition insistently calling for rest, hot fomentations, &c. Our beds are full. The patient lives either in lodgings, where he can get neither rest, baths, fomentations, &c., or in one or two rooms with the rest of his family, and an equal lack of opportunity of obtaining treatment. At times a patient who works by day has only a right to occupy a bed during the night and has to resign occupation in the morning in favour of a night-worker, who is its tenant by day. In some instances he may manage to get into an infirmary. The results of insufficient treatment are an unnecessary continuation of the patient's suffering, a prolongation of danger to the community through his infectivity, with increased expense to the nation owing to his inability to engage in productive work. We would venture to urge, as one of us (E. C.) has frequently done before, that by the help of the Ministry of Health and the County Council a small hostel should be set apart in London (and in other towns where necessary) where such cases can receive adequate treatment. The reduction of suffering, the abbreviation of the period of infection, and the shortening of the period of enforced idleness would afford a triple justification of such a step. And in certain instances patients would be willing to pay a small sum towards the expense of their treatment.

### *Cases of Vesiculitis.*

| First attack. | | | | Second or more. | | | |
|---|---|---|---|---|---|---|---|
| Right. | Left. | Both. | Total. | Right. | Left. | Both. | Total. |
| 2 | 26 | 36 | 64 | 10 | 16 | 13 | 39 |

On examining the above figures the reader will probably be impressed by the large number of patients in whom vesiculitis supervened. Personally we do not share this surprise, since, as time goes on, we realise that the incidence of vesiculitis is much greater than is usually recognised. We have no hesitation in stating that in general, when a patient has a chronic discharge which defies the ordinary routine treatment of irrigation and prostatic massage, he is suffering from vesiculitis. Further, we know that patients frequently have been discharged as cured with an infected vesicle, with an intermittently or permanently occluded duct. That this is so frequently the case is not surprising when one considers how greatly a pathological vesicle may vary in respect to size, contour, consistency, &c. So subtle and so difficult of recognition are the features frequently exhibited that it is only possible to give a definite and reliable opinion after very great experience. Special emphasis is laid on the necessity of the most complete vesicular examination. Not only is every patient examined by the clinical assistant in charge of the case, but he is also periodically referred to the director of the department or his deputy, and again when the final tests are in progress. Finally, when regarded as cured, as a result of clinical and bacteriological examination, he is again submitted to a further examination of the vesicles by the director or his representative.

We would here place on record the valuable results which accrue in suspicious cases of vesiculitis by obtaining and examining the vesicular contents apart from that of the prostate. This procedure, which was suggested by the director, Mr. Hugh Lett, has been successfully practised over a considerable period and has resulted in gonococci being detected and localised when other methods have failed.

### *Gonococcal Rheumatism.*

First attack, gonococcus was identified.

Multiple attacks and cases of chronic urethritis where the gonococcus was identified in 106 cases.

In the course of this investigation 828 consecutive patients have been examined, including 400 which have formed the basis of our previous analyses. Had we confined ourselves to the original 400 cases not more than two examples of gonococcal rheumatism would have been found. Of these 828 patients 204 were the subjects of a first attack of gonorrhœa and the gonococcus was found to be present.

*There were four cases of gonococcal rheumatism out* of the 204, as follows:—

*First Attack.*—Right knee-joint, 2; left knee-joint and left ankle, 1; right shoulder, 1. Of the 800 cases investigated 534 of the patients had either suffered from one or more attacks of rheumatism previously or were the subjects of chronic urethritis. 106 showed the presence of gonococci, leaving 428 chronic cases in which, although gonococci were not identified, yet the clinical evidence was strongly in favour of the rheumatism being causally related to the gonococcus. Of these 534 7 only suffered from rheumatism, as *follows*:—

*Multiple Attacks and Cases of Chronic Urethritis.*—Both knee-joints, 4; right knee-joint, 1; left knee-joint, 2.

We are of opinion that the percentages shown above are *much lower than those usually* described in text-books. In *many instances there was a history of* gonococcal rheumatism, antecedent to the attack of urethritis or articular trouble, for which they presented themselves at our clinic. *We are convinced that the* number of cases in which gonococcal rheumatism developed for the first time whilst the patient was suffering from an attack of *gonorrhœa, for which he* was treated at our clinic, has been much smaller than represented by the above percentages. We are inclined *to attribute these encouraging figures to the* prompt irrigation of the posterior urethra, and the thorough and systematic depletion of the vesicles and prostate of their pathological *contents as soon as* clinical safety permitted.

Unfortunately we have no access to statistical records *to enable us to compare the present incidence* of cases with that of the past or *with what* obtains in other clinics. Our opinion is that the number of patients suffering from *gonococcal rheumatism is* much less than in previous years, a possible tribute to the prompt and more efficient treatment to which patients are subjected. *Again, the wider recognition* by the public of the danger accruing to patients from the consumption of alcohol while suffering from gonorrhœa may be *another factor* productive of the reduction of cases. One outstanding fact is that there is little benefit to be obtained by only treating the joint or joints affected. Pain can be palliated in this manner, but no cure can be obtained until the causal foci present in the vesicles, prostate, &c., are actively and perseveringly treated.

*Summary of Cases (total 400).*

| | |
|---|---|
| Discharged cured | 138 |
| Still attending | 23 |
| Transferred to other clinics | 7 |
| Ceased to attend | 232 |

(Two months, 2; one month, 7; no marriage test, 181; one attendance, 42).

It may be of interest to note that of the 400 cases 138 were discharged cured. Twenty-three were sti attending when this paper was written and 7 had bee transferred to other clinics, thus leaving a residuu of 232 who had ceased to attend. *Of these*, 181 ha left without having any marriage test, 7 had le after one, and 2 after two *marriage* tests. Forty-tw *patients left after* one attendance only. There substantial reason for believing that many of thos patients who left after receiving a *prolonged* amount treatment, but who had not waited for the marriag tests, were really cured, although they naturally fa to figure in the list of cures.

The authors wish to thank Mr. Lett *for* th clinical and clerical opportunities which have mad it possible to publish these notes, *and also* for th sympathetic encourage*ment* and help which he h extended to them.

# NON-VOLATILE ALIPHATIC COMPOUNDS IN GENERAL ANÆSTHESIA.*

BY ROBERT K. LAMBERT, M.D.

THE production of full general anæsthesia has, since its introduction, almost always been accomplished by the sole use of gaseous and volatile substances. As preliminary measures various alkaloids have proved *of considerable value, but otherwise* there have been few modifications, even of the original methods of administration. The reasons for this strict adherence are evident: the large margin of safety insured, particularly by ether; the rapid absorption and excretion of gases by the lungs, enabling the anæsthetist to keep the degree of anæsthesia well under control*; and lastly, the ready* availability of these substances.

## *The Search for Ideal Anæsthesia.*

There are, however, various disadvantages to the present-day routine anæsthesia, to which, through familiarity, we have become more or less reconciled, but which should be taken into consideration: first, the occasionally deleterious and uniformly unpleasant after-effects leave much to be desired; secondly, the double passage of large *amounts* of irritating gases through the lung tissues disposes toward the production of pathological *processes*; and thirdly, operative shock is still prevalent. In this connexion there is an important psychic factor, the *emotion of fear being almost uniformly aroused*, and also the effect of the abrupt induction, which necessitates a sudden adjustment of the organism to acute poisoning.

In the search for ideal anæsthesia much is to be *hoped from the* recent introduction of further gases, such as ethylene and the like, *but there remains* another large and fertile field which invites investigation. Various relatively non-volatile aliphatic compounds have been used *for years in the anæsthetisation* of experimental animals, and there is reason to believe that, could their use be made practicable for man, the *aforementioned drawbacks* to chloroform and ether might in some respects be overcome.

The most important groups of these substances are the halogen derivatives of aldehydes and ketones (chloral, &c.), the derivatives of carbonic acid (*urethane, &c.*), and the higher alcohols (isopral, &c.). A large number of these are now used *as* sedatives and hypnotics, but few attempts *to* extend their application have been made, and those with [illegible] partial success.

Burkhardt,[1] an exponent of the intravenous technique for the administration of [illegible] in 1913 experimented upon *animals* with [illegible] aliphatic compounds. Solutions of [illegible] [illegible] veronal, medinal, chloralamid, paraldehyde, [illegible] and isopral were tried. Of these, he [illegible] hedonal and isopral to be of the [illegible] [illegible] value for the production of *full* [illegible] [illegible] reasons, however, are too [illegible] [illegible] supply of hedonal could not be obtained. Isopral-ether intravenous infusion was used by Lehrnbecher [5] in 1923, and again the chief objections raised were to the bulk of fluid necessary. Moreover, it must be admitted that the technique of intravenous administration is not readily adaptable to all circumstances.

### *The Use of a Mixture of Isopral and Hedonal.*

Many of the obstacles met with by these and other workers seem to have been overcome, in experiments on animals at least, by the employment of a mixture of isopral and hedonal, to be described. An ideal anæsthesia would seem to be one by which the patient could be slowly and pleasantly rendered more or less insensible in his room, easily tided over to surgical anæsthesia in the operating theatre, and in which, after operation, he would return to deep, but not too protracted, physiological sleep. The idea of using aliphatic compounds alone to attain this end was discarded, because at the present time they are insufficiently controllable in their action, and do not provide a large enough margin of safety. With a completely safe dose which will produce the proper degree of stupor, however, the benefits of superimposed ether or chloroform should be obtained, the transition stage become imperceptible to the patient (as described by Mertens [2]), and the quantity of gaseous or volatile anæsthetic be greatly reduced, while its administration might be stopped early in the operation.

By the use of a combination of isopral and hedonal many of these desiderata have been attained in animal experiments. Administration of bulky infusions is unnecessary, the late excitement, sometimes occurring after isopral alone, can be eliminated, and greatly reduced doses of hedonal can be employed. A careful plotting of time-intensity curves (see figure) makes it possible to avoid dangerous super-imposition of gaseous anæsthetics before the original non-volatile ones have reached their maximal effects, and also makes it possible to foresee with fair accuracy the duration of anæsthesia.

*Isopral.*—Trichlorisopropylalcohol, or isopral, is readily soluble in alcohol and ether, and slightly soluble in water. It is absorbed very rapidly by the mucous membranes of the alimentary canal and the subcutaneous tissues. Excretion takes place for the most part as trichlorisopropylglycuronic acid, about two-thirds being excreted in this form by rabbits (Heffter [7]). Only a trace is excreted by the lungs. The action of isopral is by no means limited to the cerebrum; the bulb, spinal cord, and sympathetic system are also affected. Very little alteration in the circulation occurs with narcotic doses, there being a slight fall in blood pressure. Toxic doses first affect the respiratory centre, and later the heart. Total anæsthesia produced by isopral alone has on occasion been followed by excitement in animals (Burkhardt [1]), and the same has occurred after its use with chloroform in man (Kleinschmidt [3]).

The hypnotic dose for man is from 0·5 g. to 1 g. (in toto), and up to 8 g. (in toto) have been given with safety (Mertens [2]).

The table of doses for animals (Heffter [7]) is:—

| | Hypnotic. | | Lethal. |
|---|---|---|---|
| Rabbit .. .. | 0·2 g. per kilo | .... | 0·9 g. per kilo |
| Dog .. .. | 0·093 g. „ | .... | 0·6 g. „ |
| Cat .. .. | 0·09 g. „ | | 0·25–0·3 g. |

*Hedonal.*— Methylpropylcarbinolurethane, or hedonal, is also soluble in alcohol and ether, but with difficulty in water. Absorption and excretion both take place very slowly, but there is complete oxidation in the body to carbon dioxide, water, and urea. Sleep effected by hedonal is closely akin to the physiological, the respiration and blood pressure being practically unaltered, save in the normal manner. Anæsthetic doses in man and animals produce no stage of excitement, but the duration of anæsthesia is protracted.

The hypnotic dose for man is from 1·5 g. to 2 g. (in toto). A dose of 8 g. (in toto) has been followed by untoward symptoms (Lederer [4]).

The table of doses for animals (Heffter) is:—

| | Hypnotic. | | Lethal. |
|---|---|---|---|
| Dog .. .. | 1–8 g. (in toto) | .... | 10–15 g. (in toto) |
| Cat .. .. | 0·3–0·8 g. „ | .... | 1 g. „ |

The differences between the physiological actions of hedonal and isopral are striking. The former is slow of onset, while with the latter almost immediate effects can be perceived. That this is due to a different rate of absorption and not to immediate cellular effect has been very kindly demonstrated by Prof. A. J. Clark, who has perfused the isolated frog's heart with solutions of the drugs. Under these conditions, indeed, hedonal produces a more rapid action than isopral. The intact animal, however, absorbs and apparently excretes isopral much the faster of the two. The difference in the rate of action of the two drugs when given hypodermically is shown by the curves (see figure) (this difference is, of course, not observed with intravenous administration, where there is no factor of absorption).

As has been mentioned before, the use of isopral alone has been unsatisfactory. When hedonal is administered alone, by any means other than the intravenous, there is too long a latent period before the summit of the curve can be reached, for practical purposes. By mixing the two, however, in the proper proportions an effect can be obtained in a short time, while the hedonal action occurring late apparently eliminates excitement.

Administration of fixed narcotics via the alimentary canal is unsatisfactory not only because of the great variability of action, but because here again a considerable lapse of time is required before the drug can have its full effect. The intravenous use would perhaps be the route of choice were it not for the fact that these preparations are only sparingly soluble in water making an unpleasantly large bulk necessary. It has been found that the physical properties of isopral and hedonal make a mixture peculiarly adaptable for injection, subcutaneously or intramuscularly. Both are solids, hedonal melting at 76° C. and isopral at 49° C. When warmed together in certain proportions the melting points are sufficiently lowered to cause liquefaction. There is no ascertainable chemical change, and refrigeration will often cause a distinct separation into layers. Moreover, shaking the mixture in water does not split off chloral. A good proportion to produce a rapid induction of narcosis, without too sudden ataxia or too sustained an effect, appears to be two parts by weight of isopral to one of hedonal, which is given intramuscularly. The mixture, made by warming the ingredients together, remains fluid at room temperature; but a small quantity of sterile olive oil is added to insure this being the case, and at the same time is useful in bringing the bulk of the mixture from a little below, to exactly three parts by volume—i.e., 2 g. isopral + 1 g. hedonal = 3 c.cm.

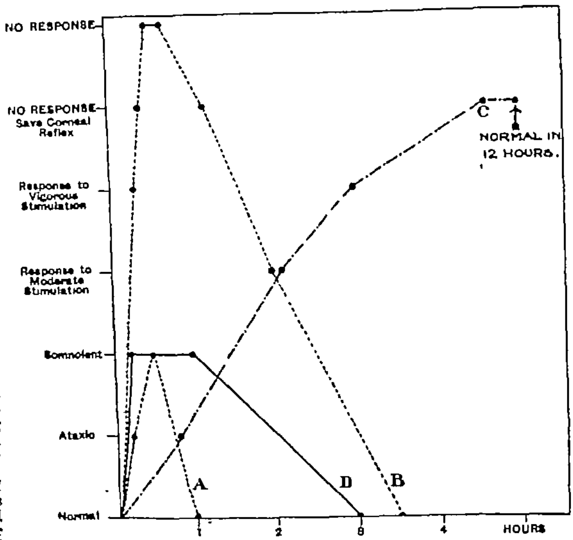
Because of the slight volatility of these substances when warmed, it is deemed wiser to mix them by means of aseptic technique while in their dry state, and then to add sterile olive oil rather than to attempt sterilisation of the mixture as used. (For the same reason tight stoppers and not cotton plugs should be used in containers.) Bacteriological cultures of the mixture made in the above manner have failed to yield organisms of any kind; in fact, Howard and Stimpert [illegible] have recently shown that there is considerable bactericidal action of isopral.

The following table of doses has been determined for rats by a series of experiments. The preparations were given subcutaneously, the isopral being warmed above its melting point and given directly, and the hedonal dissolved in a small quantity of 50 per cent. alcohol. (Control rats injected with similar quantities of 50 per cent alcohol were, of course, observed.) With reference to this table it must be borne in mind that the apparent effective dose for smaller animals is of little value as applied to the dose for man, because minor psychic and physical changes are not readily demonstrable in the animals.

The considerably lower margin of safety provided by hedonal is noteworthy.

| — | Minimal effective dose. | Anæsthetic dose. | Minimal lethal dose. |
|---|---|---|---|
|  | per kilo. | per kilo. | per kilo. |
| Isopral .. .. | 0·05 g. | 0·25 g. | 0·30 g. |
| Hedonal .. .. | 0·075 g. | 0·10 g. | 0·28 g. |
| 2 isop. + 1 hedon. | 0·05 c.cm. | 0·30 c.cm.<br>(or 0·25 c.cm./k. intramusc.) | 0·60 c.cm.<br>(or 0·40 c.cm./k. intramusc.) |

It was found that a dose of 0·15 c.cm. per kilo of the I.-H. mixture given intramuscularly was very useful for determining the effects of superimposed gaseous anæsthetics in cats. By leaving the cat in a dark, quiet place for about two hours after the injection a state of somnolence was obtained, so that the cat could only be roused by considerable agitation.



The effect of isopral, hedonal, and a mixture of the two on cats. A, 0·05 g. isopral per kilo. B, 0·25 g. isopral per kilo. C, 0·20 g. hedonal per kilo. D, 0·10 c.cm. isopral-hedonal per kilo (2 parts isopral to 1 part hedonal by weight, plus olive oil to make 3 parts by volume).

It is necessary to keep animals quiet following an injection. The rapidly progressive ataxia produces fright, and accordingly a certain amount of excitement in animals which remain active through one cause or another. Animals which are kept quiet and soothed always evince happiness and contentment. It is possible to overcome part of the action of the drugs by continual psychic stimulation—e.g., by placing a mouse within the cat's range of vision.[†]

A series of laparotomies were performed upon cats under ether which had been preceded by sufficient isopral-hedonal to produce stupor (0·15 c.cm. per kilo), but not full anæsthesia. These were controlled by another series in which ether alone was used. The degree of anæsthesia and blood-pressure level remained strikingly uniform in the first series of cases with doses of about 10–15 c.cm. ether, despite numerous shock-producing manipulations. In the controls, however, it was necessary to give about three to four times as much ether during the operation, and under no circumstances could as even an anæsthesia be obtained, nor could the blood-pressure level be kept as constant. In the control animals vomiting occurred soon after the administration of ether was stopped, whereas the animals under united anæsthesia passed from full anæsthesia to post-operative sleep which lasted several hours, and little vomiting was observed.

Intraperitoneal injection of the same dosage will produce complete anæsthesia within nine minutes, but the use of this route has not yet been carefully investigated. As yet, small doses only have been given to man. Nevertheless, general effects have been observed from as little as 0·5 c.cm. subcutaneously. At the site of a subcutaneous injection there is slight localised soreness and œdema, persisting about two hours, but no redness. But as with several other moderately irritating substances, it can be freely used intramuscularly without unpleasant local effect. A further mixture with novocaine has not been injected, because of a slight liberation of chlorine which takes place. The region of nerve trunks must be carefully avoided, as the isopral is an alcohol, and has been shown to paralyse an injected nerve.

The practical application of these drugs to man is now being attempted at the surgical unit of the University College Hospital, and it is hoped that other investigators will find the problem worthy of their attention.

*Summary.*

It is suggested that by the preliminary use of non-volatile aliphatic compounds in general, and more particularly by a mixture of isopral and hedonal, the following benefits may result: (1) The patient may be made drowsy and content, or completely somnolent before leaving the ward. (2) The completion of anæsthesia by gaseous anæsthetics may be facilitated, and the duration of their use be reduced. (3) After operation, the patient may fall into prolonged and healthy sleep.

Because up to date only small and tentative doses have been administered to man these benefits have not yet been obtained, but the results of animal experimentation encourage the hope that they will be found to accrue.

I wish to express my gratitude to Prof. A. J. Clark and Prof. C. C. Choyce for their interest and help, and to Dr. H. D. Wright for making the necessary bacteriological observations.

[†] In this regard it may be of interest to mention the commonly accepted belief that morphia always produces excitement in cats. In the physiological laboratories of the University College it has been found that morphia may be given to cats if only a little skill is used in soothing the animal into a quiet condition during the injection. The excitement said to be due to the morphia is the result of manipulation and may be avoided.

# HERPES ZOSTER IN SPONTANEOUS SUBARACHNOID HÆMORRHAGE.

By W. J. ADIE, M.B. Edin., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN, CHARING CROSS HOSPITAL; PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE.

The object of this note is to record the occurrence of an herpetic eruption of nerve-root distribution in two cases of spontaneous subarachnoid hæmorrhage. This symptom was not present in nine cases I have seen myself, nor, so far as I know, has it been observed by others.

Case 1.—A woman, aged 42, previously healthy, was found unconscious at her bedside and removed to the St. Marylebone Infirmary where I saw her on the fourth day of her illness. She was then conscious but irritable and confused; she resisted attempts to examine her and, except for repeated complaints of headache, was unable to give an account of her symptoms. She presented the classical picture of acute cerebro-spinal fever with extreme rigidity of the neck, Kernig's sign, and pyrexia. Ophthalmoscopic examination revealed recent papillœdema of both discs; on the right side, beyond the swollen disc, were several large collections of blood, very dark, bulky, with rounded edges not at all flame-shaped, and quite unlike ordinary retinal hæmorrhages. It looked as if drops of blood had been allowed to fall upon the retina from a large-bored pipette. On the left side, in addition to several large round hæmorrhages, there was one, very large, with a horizontal upper and a rounded lower border, in size and shape like half a threepenny-piece. The abdominal and thoracic viscera appeared to be healthy; the urine was free from albumin and sugar; the Wassermann reaction was negative in the blood and cerebro-spinal fluid. Lumbar puncture yielded cerebro-spinal fluid under increased pressure intimately mixed with blood. The patient improved steadily for several weeks but died rather suddenly, apparently from a recurrence of meningeal hæmorrhage. During the period of improvement her mental state was exactly that known as Korsakoff's psychosis, a condition I have seen in others recovering from the disease. The body was not examined after death, but the history of unconsciousness with recovery to a condition indistinguishable from cerebro-spinal fever, the subhyaloid hæmorrhages, the bloody cerebro-spinal fluid, and the mental state in the later stages leave little room for doubt about the diagnosis which receives confirmation from the mode of death.

In this patient a copious eruption of herpetic vesicles appeared on the upper part of the chest and over the deltoid muscle on the left side in the area of skin supplied by the fourth and fifth cervical sensory nerve-roots. It was present when I saw her first on the fourth day of her illness.

Case 2.—A man, aged 37, previously healthy, complained one evening of severe headache of sudden onset; during the night he was restless and rambled in his speech; by the morning he was, in his wife's words, "conscious and no more." When I saw him at Charing Cross Hospital on the fifth day of his illness his condition was that of a man with fully-developed acute cerebro-spinal fever. Before I saw him bloody cerebro-spinal fluid had been withdrawn by lumbar puncture and spun in a centrifuge; the supernatant fluid was yellow; this proved that blood had been present in the fluid for many hours and was not due to a faulty puncture. The Wassermann reaction was negative in the blood and cerebro-spinal fluid; the urine was normal. The patient died on the eighth day. After death Dr. A. Piney found blood in the subarachnoid space over the whole surface of the brain. Around the middle cerebral artery on the left side, about 1 inch from its origin, was a recent blood-clot about the size of a walnut. A probe within the artery met an obstruction on reaching the centre of the clot; careful washing and dissection revealed a ruptured aneurysm on the artery large enough to contain a cherry stone. The brain and cerebral arteries were otherwise perfectly healthy, as were all the other organs of the body.

In this case, where the diagnosis was confirmed after death, an herpetic eruption appeared on the right side of the chest in the lower part of the area supplied by the fourth cervical sensory nerve-root. The patient's wife noticed it first on the third day of the illness.

### *Remarks.*

When confronted by the symptoms of meningitis in a patient free from disease in which inflammation of the meninges is a probable complication, and beyond the age at which tuberculous meningitis usually occurs, the physician should think rather of meningeal hæmorrhage than of meningitis itself, for the former is much the more likely cause; and if herpes zoster is a symptom it is still more likely, as herpes, except on the face, is almost unknown in meningitis due to organisms. The cases described above exemplify the two common forms of spontaneous subarachnoid hæmorrhage. In one form there is coma leading to death or recovery to a condition simulating acute meningitis, in the other the symptoms are those of meningitis throughout. In both of these cases the bloody cerebro-spinal fluid indicated the correct diagnosis; in one the characteristic subhyaloid hæmorrhages provided evidence that blood had been shed around the base of the brain. In young people the blood usually comes from an aneurysm which forms at the site of a congenital defect in an artery, near its origin from the circle of Willis. In older patients a ruptured arterio-sclerotic vessel is the commoner source. In some cases in which blood has been found evenly distributed throughout the subarachnoid space careful search has failed to reveal a ruptured vessel, and the condition is attributed to a general "weeping," analogous to that which is said to occur in "true gastrostaxis" and in certain cases of hæmaturia. My own feeling is that the proportion of cases in which rupture of a single vessel is discovered will increase with the amount of care that is used in searching for it.

The potency of blood free in the cerebro-spinal fluid is shown by the severity of the irritative phenomena in this disease; headache is never more sudden and severe, nor is neck-rigidity or Kernig's sign ever more distinct in true meningitis than in some of these cases. It is not difficult to account for herpes zoster, for the spinal subarachnoid space extends outwards around the posterior roots, sometimes as far as the root ganglion. The anatomical arrangement differs in different individuals and in the same individual at different spinal levels. I assume that in my cases blood in the spinal subarachnoid space reached certain ganglia by this route, and then by irritation produced the same result as it does when hæmorrhage occurs within the ganglion itself.

I am indebted to Dr. Basil Hood, medical superintendent, St. Marylebone Infirmary, and to Dr. W. Cecil Bosanquet, senior physician, Charing Cross Hospital, for permission to publish these cases.

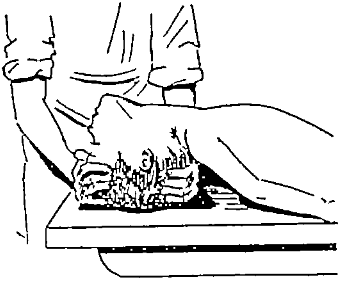
# AN EASY METHOD OF PERFORMING TRACHEOTOMY.

By KENELM H. DIGBY, M.B., B.S. Lond., F.R.C.S. Eng.,
HO TUNG PROFESSOR OF CLINICAL SURGERY AND PROFESSOR OF SURGERY, HONG-KONG UNIVERSITY.

Any medical man, whether experienced in surgical work or not, may be suddenly called upon to perform a tracheotomy. In a fat, struggling, nearly asphyxiated child, with the veins in the neck distended with blood, this small operation done in the usual way, may become formidable to one without much practice. Time may be wasted, blood may enter the trachea, and the incision in the trachea may be wrongly made.

By the technique advocated below the operation becomes almost bloodless, is freed from all possible confusion; the trachea is held steady and is clearly exposed to view and no blood can enter. After a little practice the operation can be performed within one minute. A preliminary note written in conjunction with my then house surgeon, Dr Yue Man Kwong, on this as well as on other points in connexion with tracheotomy appeared in the *Caduceus* for May, 1924, and was subsequently reprinted in the *China Medical Journal* Further experience with this method has seemed to justify its wider publication.

FIG 1.



*Technique.*

The child is held lying on its back on a flat surface. An assistant on the child's left places his right hand on the child's forehead and his left hand on the child's occiput and extends the head to the maximum point. The chin is raised so far that the front of the neck is a flat surface from the sternum to point of chin (Fig 1) This is necessary to enable the subsequent use of artery forceps without their bows being obstructed by the point of the chin (Fig 10) A median skin incision is made 1½ inches long vertically downwards starting from the *upper* border of the cricoid cartilage. The deep fascia uniting the sternohyoid muscles is divided vertically (Fig 2). The cricoid cartilage is exposed and the fascia, attached to its lower border, is incised transversely to expose the commencement of the trachea (Fig 3) A single closed pair of pressure forceps is passed downwards and backwards close to the trachea and behind the isthmus of the thyroid gland (Figs. 4 and 5) A very slight opening and shutting of the forceps may assist their passage. The tissue thus raised is clamped close to the middle line first by one pair of forceps (Fig 6) and then by a second pair placed parallel (Fig 7) The fascia and thyroid isthmus between the forceps are then divided and the two pressure forceps are each rotated in a lateral direction through 90° and the handles are slightly depressed so as to raise the points. The rotation of the forceps usually peels the tissues from the trachea sufficiently to expose its anterior aspect, but a touch of the knife at either side will fully lay bare the front of the trachea (Fig 8) As the thyroid gland is intimately connected with the trachea and the cricoid cartilage, this manœuvre raises the trachea to the level of the skin, exposing the first four rings with utmost clearness (Fig 9) The vertical incision (through the second, third, and fourth rings) should not be made by the "guarded stab" but should be gently incised with the knife held pen holder fashion, the little finger of the right hand resting on the upper border of the manubrium. The stab is to be avoided because the trachea is flattened antero-posteriorly by thus being brought to the surface, and the posterior wall would be in danger (Fig 9)

# THE TREATMENT OF PULMONARY TUBERCULOSIS WITH SANOCRYSIN.[1]

BY T. R. ELLIOTT, C.B.E., D.S.O., M.D. CAMB., F.R.C.P. LOND., F.R.S.,
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON.

SANOCRYSIN and its complementary antituberculin serum have now been used in England by a limited number of observers for a little more than a year. We tried it on human patients because Danish workers had stated that with this drug they could arrest or cure tuberculosis when implanted experimentally in calves. The proof of such laboratory result with animals would compel clinicians to essay every possible means of adapting the treatment to human cases. Mollgaard's experiments on the calf have been criticised, but not, I think, refuted. I hope that we may hear more information this evening on that point, for it lies at the very heart of the whole matter.

Turning, then, to observations on human cases, the first question is that of the movements of the drug through the body. Sanocrysin is a very soluble thiosulphate of sodium and gold, containing 40 per cent. by weight of the latter metal. It is given intravenously as a solution in 10 c.cm. of water, and care is needed to prevent the needle from leaving an indelible black spot in the skin. For the first few days after an injection gold can be detected in the urine easily, and to a less amount in the fæces. Frandsen, of Copenhagen, has made numerous observations on human cases and found that only 30 per cent. is so excreted; the rest stayed indefinitely in the body. The only analysis of which I am aware as giving information about the places of storage of that gold were made by Mr. C. R. Harington in two of my cases that died. The tissues were ashed and the metallic gold extracted and weighed.

The first case died one day and the other 27 days after the last injection. The rapid excretion of gold in the urine is illustrated in the first case, where the contents of the bladder at death, altogether apart from urine previously voided, held nearly 5 per cent. of the gold given. But a large proportion remains stored in the body; Frandsen said 60 per cent. We recovered only 10 per cent. in the organs analysed—namely, the liver, kidneys, and lungs—but these organs formed only one-twentieth of the body-weight, and therefore the distribution elsewhere, in muscles or in the bones, as with lead, cannot be at a similar concentration. The gold tends to accumulate in the kidneys, as is shown in the second case after 27 days. In this patient it had definitely disappeared from the lungs, which were the only site of tuberculous infection. The drug is therefore not held up for long in tuberculous areas. Its concentration in the kidney was 60 times as great as its concentration in the liver. Even so this patient did not show albuminuria.

We must therefore remember, when attempting to gauge the dosage of sanocrysin, that the concentration in the blood and around the tuberculous areas falls off in a few days, but that a large proportion of the total gold given is stored in the body and that it accumulates especially in the kidneys.

### *Clinical Effects of Administration.*

The obvious clinical results of administering the drug, in a dose of ½ g. followed three or four days late by 1 g., may be briefly recapitulated. There is generally a little nausea, and the patient may vomit once or twice in the first few hours. Some complain of a persistent metallic taste in the mouth with dislike for food. There may be a slight headache. That is all, except in patients with active and well-vascularised tuberculous infections. In these the temperature rises; there is often an intense and widespread rash, scarlatiniform or morbilliform; there may be albuminuria with renal casts, but never any œdema or serious diminution of urine. The general reaction is not one of severe discomfort. But if the drug is pushed unduly there may suddenly develop alarming features, either of hyperpyrexia or of so-called "shock" with fall of temperature, a rapid and weak pulse, hurried breathing, and general collapse. Also, excessive dosage may lead to intense albuminuria, to persistent vomiting or diarrhœa, with complete distaste for food and rapid loss of weight. Most of these features were ascribed by the Danish physicians to the liberation of tubercle toxins from bacilli killed by the sanocrysin, and to combat them a special antituberculin serum was prepared. The features of the reaction in the rash, though not the albuminuria, do closely resemble those that were seen with big doses of tuberculin when that method of treatment was first introduced.

But whichever be the cause, whether the tubercle toxins or the ill-effects on the tissues of an excessive concentration of the gold salt, there is very real danger in an ill-regulated use of sanocrysin. There may be sudden or progressive exaggeration of the more serious symptoms of the tuberculous infection, or there may be a poisoning of the kidney, of the liver, and even of the skin, with a drug dermatitis that is quite distinct from the relatively transient rash. All these dangerous features are far more liable to arise in the sanocrysin treatment of tuberculous patients than in the use of salvarsan for syphilitic or other infections.

### *Results of Treatment.*

I have treated only 11 cases. Four of these may be discarded, three being of glandular or bony infection and giving no special information, while the fourth was a patient in whom no diagnosis was ever made. That leaves only seven, and two of these died. This number is far too small to justify any sound conclusions, and I can only submit the results of my own experience in the form of impressions.

In the first place, I think that the treatment has not done harm to any case under my care. This statement requires some amplification. There were two deaths during treatment, those from which the tissue analyses were made. The first was a hopeless case of tuberculous meningitis; the second was a patient with rapid and very extensive caseation, a galloping consumption of the lungs. Here one can only urge a personal judgment, that the patient was desperately ill before treatment was commenced, that he survived a month after the cessation of treatment, and that his downward progress did not seem to have been much influenced for the worse by the sanocrysin treatment.

There was a third case in which for many months I thought that harm had resulted. This was the first case treated in England. At that time the principle which we in London had received from the Danish work as a guide in our trials of the drug was that sanocrysin is bactericidal, but that the tubercle bacilli may soon become resistant to the drug. Therefore it was necessary to push the sanocrysin heavily at the outset and fight at once for victory, even at the cost of some distress to the patient. Grave reactions were to be countered by the use of the special antituberculin serum. It is likely that the acceptance of this principle led to some of the difficulties or disasters that at first were encountered in treatment. Latterly it has been the custom in Denmark and elsewhere to give smaller doses at longer intervals. Serum is then rarely needed, for the patient is not made ill by the reactions. Of course, it may be that this gentler procedure is not the best way of advancing the cure, but at present one can only judge the problem clinically, for there are no tests available on the pathological side, by examination of the blood serum or otherwise, which can serve to inform clinicians about the reactions which occur.

---

[1] Being a contribution to a discussion at the combined Sections of Medicine and Therapeutics of the Royal Society of Medicine on Jan. 12th, 1926.

To return to the particular patient. She was a girl of 18, of very poor physique and with bilateral apical tuberculosis. During three months she remained in hospital under good routine treatment, yet with tubercle bacilli always present and no improvement. She was then treated heavily with 0 g. of sanocrysin and with serum, for she had two dangerous collapse reactions. Subsequently she had incessant vomiting for a week, then anorexia and loss of weight. There was albuminuria to 1 5 per cent. On discharge from hospital she was still thin and ill, but she refused to go to a sanatorium and remained at home in a quite poor environment. But she improved steadily. She has now, a year after her treatment, put on a stone in weight. She is plump and well with neither cough nor bacilli in the sputum, and the pulmonary disease is completely arrested. Her urine is normal. My earlier impression was therefore mistaken and in her case the drug not only did no serious harm, but seems to have done good, for her prognosis was originally a poor one. In all subsequent cases I have used less intensive treatment, have rarely employed serum, and have seen no suggestion of harm as the result of giving sanocrysin, but, on the contrary, the treatment has seemed to coincide with a real improvement in each patient.

### *A Specific Action?*

Secondly, the sanocrysin appeared to have a specific action on tissues infected by tuberculosis. This was suggested by an unusually inflammatory vascularisation of the tuberculous areas in my two cases which were examined *post mortem*. In other pulmonary cases which did not die there was evidence of a focal reaction in some pain in the chest, slight dyspnœa, and often an increase for a while of adventitious auscultatory sounds. There was no proof of the tubercle bacilli being killed directly by the gold salt; but the inflammatory reaction in the tuberculous areas was attended by the escape into the circulation of toxins which produced general bodily reactions similar to those caused by large injections of tuberculin. Such general reactions were seen only in patients with active and well-vascularised tuberculous lesions. But the converse deduction—namely, that a well-marked reaction to sanocrysin is proof of an active tuberculous infection—cannot yet be made, for, so far as I am aware, no clinician has tested the drug in a sufficient variety of other diseases. I tried sanocrysin in one case of tuberculosis of the cervical glands and in another of a tuberculous fistula from the shoulder-joint. There was no reaction at all and no benefit. The drug was not injected into the fistulous tract itself.

A satisfactory type of reaction occurred in a patient 18 years old, who had an acute and extensive infection of the left lung and less than two months' history of illness. On account of the apparently rapid spread of infection he was kept under preliminary observation in hospital for only ten days. An injection of 1 g., after a preliminary ¼ g., caused a prolonged rise of temperature accompanied by a generalised rash. The rash recurred briefly with the next injection. There was no albuminuria and no uncomfortable malaise. In all the patient received 4¼ g. in two months. His general condition improved rapidly after the third injection, his fever ceased, and the tubercle bacilli tended to disappear, while the cough and sputum became trifling. He went home and two months later had gained 0 lb. in weight, while feeling active and taking long walks. Subsequently he was admitted to a sanatorium from which satisfactory reports of his progress have recently been received. I think that this case was an example of an exceptionally rapid abatement of what appeared to be a serious tuberculous infection.

My impression has been that the best results are seen in patients who react at first with sharp fever and rash. The next injection must then be delayed for a week after the fever reaction or even much longer so as to ensure that the following reaction shall be of a less severe character. If the injections are spaced widely enough dangerous reactions and loss of weight can be avoided and there will never be more than a trifling albuminuria. The albuminuria is certainly related more to the total quantity of sanocrysin given and to the time intervals between doses than it is to the severity of the reactions in fever and in rash.

Lastly, I wish to refer briefly to two cases of which some account has already been published. One was a girl, aged 20, with a localised collection of fluid in the lower abdomen reaching nearly to the umbilicus. The diagnosis of tuberculous peritonitis was not proved by opening the abdomen, but there was a history of pleurisy six years before, leaving persistent physical signs and changes in the X ray appearance of the chest, and also of tuberculous peritonitis three years before. The patient was treated in hospital for three months without improvement. She was then given sanocrysin, 4½ g. in 17 days. She reacted with fever and a rash. At the end of the treatment the fluid had completely disappeared. Five months later there was nothing abnormal to be found on pelvic examination; she had put on more than a stone in weight and she has now returned to work. The diagnosis was reasonably certain and the striking feature of the case was the extremely rapid disappearance, in three weeks, of all physical signs in the abdomen simultaneously with sanocrysin treatment.

The other case was one of equally rapid improvement under sanocrysin, but in which the diagnosis of tuberculous infection was not firmly based. A boy of 14 developed tuberculous glands in the neck. These were excised and the infection in them proved. He had also had enlargement of the hilum glands in the chest. After the operation on the neck he developed signs of pulmonary infection. This continued and ultimately the X rays showed a persistent area of consolidation in the right lower lobe. But there was no sputum and there were no tubercle bacilli in the stools. The boy was under observation for four months in hospital, during which time fever persisted, and there was progressive loss of weight. When treatment with sanocrysin was commenced at the end of this time he was critically ill. He received 1½ g. in six days. There was a sharp pyrexial reaction and a rash. Soon after this his fever abated and finally ceased. He rapidly regained weight, ultimately putting on 2 st. The signs in the chest slowly lessened and three months after treatment the radiogram of the lung was almost normal.

The clinical history and, though this is rather begging the question, the reaction with fever and rash to sanocrysin do suggest that the acute pulmonary infection was due to tubercle. In any case the treatment coincided with an extraordinarily rapid recovery in a patient who up till then had been gravely ill—so no harm was done.

### *Conclusions.*

As I emphasised at the outset, the number of patients whom I have treated with sanocrysin is very small. They were selected as examples in whom any quick improvement of their diseased state would not have been expected under the ordinary routine of treatment. The prognosis of a tuberculous infection is hazardous, even for physicians with long and special clinical experience; and that I do not possess. But in the cases that I have quoted the turn for the better occurred almost simultaneously with the treatment by sanocrysin; and though coincidences do occur in a most misleading fashion in practical medicine it seems to me unlikely that all these four should have been only chance coincidences. My own opinion is in full accord with that of Prof. Faber, of Copenhagen, a physician of very wide clinical experience, who started the use of sanocrysin with perhaps a prejudice against it, but summed up his results in a statement that in sanocrysin he found a drug that produced more rapid improvement in pulmonary tuberculosis than be obtained by any other method of he knew.

# ACUTE HÆMORRHAGIC NEPHRITIS IN CHILDREN.

BY W. G. WYLLIE, M.D. EDIN., M.R.C.P. LOND.,
LATE MEDICAL REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;

AND

ALAN MONCRIEFF, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR, MIDDLESEX HOSPITAL: LATE HOUSE PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE occurrence of a hæmorrhagic form of acute nephritis has long been recognised by children's physicians in this country, and Sir Thomas Barlow referred to it in his clinical teaching at the Hospital for Sick Children, but it is noticeable that as a distinct type of nephritis it has hardly yet found its way into the text-books of medicine. Our attention was called to this condition by a striking case, recently admitted under the care of Dr. Robert Hutchison, a full account of which appears below, and a search of the records of the hospital for the last three years has revealed the fact that this type of nephritis is by no means uncommon. The clinical features are sufficiently obvious to enable a case to be placed in this category and differentiated from other forms of nephritis by a perusal of the notes. A classification of 87 cases of nephritis of all varieties, acute and chronic, is set out in Table I. In passing it may be said that we have been guided in our classification of chronic nephritis by the amount of albumin in the urine and the specific gravity, the amount of œdema, the urea and cholesterol contents of the blood, and the urea-concentration test, keeping closely to the work of MacLean.

TABLE I.—*Analysis of 87 Cases of Nephritis Admitted to Great Ormond-street Hospital during the Three Years July, 1922, to June, 1925.*

| | Cases. | Per cent. |
|---|---|---|
| Acute nephritis .. .. .. | 23 .... | 26·4 |
| Acute hæmorrhagic nephritis .. | 22 .... | 25·3 |
| Chronic nephritis .. .. | 42 .... | 48·3 |

The cases of chronic nephritis were further classified as—

| | |
|---|---|
| Chronic parenchymatous nephritis .. | 23 |
| Chronic interstitial nephritis .. .. | 19 |

of which eight were examples of renal dwarfism with bone changes.

### *Two Types of Acute Nephritis in Children.*

It will be seen, therefore, that acute nephritis in children can be classified under the two headings of hæmorrhagic, and of what has been variously called acute parenchymatous or acute "exudative" nephritis. The latter is the form described fully in most text-books, and is characterised in a typical case by general œdema, headache, vomiting, a rise of temperature, a reduction in the quantity of urine, which is albuminous to a degree exceeding that accountable for by the amount of blood which may be present during the period of oliguria. Large numbers of casts are found of all varieties and the blood pressure is often raised. The hæmorrhagic variety is distinguished from this by the occurrence of a more benign disease, in which blood appears in the urine quite suddenly, sometimes during, but usually a few days after some acute or subacute infection of the naso-pharyngeal region, and may continue to be passed in smaller quantities for several days or weeks. The question of the focus of sepsis will be discussed more fully later. There is rarely any vomiting or headache associated with the onset, œdema, if it occurs at all, is slight, seldom more than some puffiness of the eyes, which disappears rapidly. The urine is little, if at all, reduced in quantity and contains a large amount of blood, often remaining red or very smoky for several days, and the amount of albumin present can be largely accounted for by the degree of hæmaturia. In about one-third of our cases a few casts were found in the urine, and these were either epithelial, granular, or blood casts. Retinitis is not observed. There is usually no rise of blood pressure and the heart is not enlarged. The blood-urea is very seldom raised, and the urea-concentration test, where it has been carried out, is within normal limits. The condition subsides quickly in most cases, sometimes even in a few days, but usually in a few weeks, the blood and albumin in the urine gradually diminishing in almost equal proportions.

### *Ætiology of Acute Nephritis in Children.*

Streptococcal infections are the commonest precursors of acute nephritis in children, but the staphylococcus and pneumococcus may also be responsible. In our series of cases bacterial investigations of the urine have been disappointing, but in one case of hæmorrhagic nephritis streptococci were obtained from a parotid abscess, and a closely similar, if not identical, organism was isolated from the urine. With regard to a focus of sepsis it must be pointed out that while it is generally supposed that acute nephritis is associated with some such definite cause, the localisation of this source of infection is more often traceable in the hæmorrhagic than in the "exudative" or parenchymatous type, and, indeed, forms a striking feature of the former condition.

Throat affections predominate in the history of hæmorrhagic nephritis. Tonsillitis, with or without an associated otitis media, is by far the commonest cause. Cervical adenitis, carious teeth, parotitis, and pneumonia are other certain causes. Purpura, impetigo contagiosa, and naso-pharyngitis have also been cited by various authors as predisposing to this condition. Although it is true that a history of one or other of these conditions quite often precedes an attack of the "exudative" or parenchymatous variety of nephritis, yet in many cases of this type no cause can be traced. Nephritis as a complication of scarlet fever and the other exanthemata is usually believed to be of the "exudative" type.

A study of Table II., in which the clinical features of our 22 cases of hæmorrhagic nephritis are set out, and the following description of Case 14, by which our attention was first drawn to the condition, will serve to bring out certain further points which can then be discussed.

### *Clinical Record.*

CASE 14.—K. A., a girl, aged 8 years 8 months, admitted in January, 1925. In September, 1923, she ran a high temperature on and off for six weeks and passed smoky-coloured urine. In March, 1924, blood again appeared in the urine, associated with a rise of temperature, and in the attack the right ear ached and there was a discharge from it. In July, 1924, there was a further attack of hæmaturia. The child then remained well until January, 1925, when hæmaturia reappeared, and there was some pain in the right ear and a slight rise of temperature. On admission there was no œdema present save for slight puffiness under the eyes. The urine was smoky, containing blood and albumin, and a catheter specimen was free from any organisms. Microscopically, the urine contained red blood corpuscles and granular, epithelial, and hyaline casts. A cystoscopic examination revealed nothing abnormal, and specimens of urine obtained by ureteric catheterisation showed only the changes already mentioned. The blood count was normal and the complement-fixation test for tuberculosis was negative. A guinea-pig was inoculated with urine, but when killed gave no evidence of tuberculosis. The blood-urea was 37 mg. per 100 c.cm. and the blood cholesterol 126 mg. per 100 c.cm., and a urea-concentration test was normal (3·1). There was no enlargement of the heart and the blood pressure was 120 mm. of mercury.

On Jan. 23rd, 1925, Mr. Twistington Higgins ope
upon the right ear and removed some chronic granul
tissues from the tympanic antrum. Blood was still pre
in the urine when the patient developed whooping-c
and had to be sent home, where she was said to have n
a good recovery and the urine became normal in appeara
When seen on May 21st, 1925, the urine contained a t
of protein, some red blood corpuscles, and no casts.
urea-concentration test was again normal (3·9), bl
pressure was 118 mm., and there was no enlargement
the heart.

TABLE II.—ANALYSIS OF 22 CASES OF HÆMORRHAGIC NEPHRITIS, 10 BOYS AND 12 GIRLS.

| Year. | Case. | Age. | Symptoms of onset. | Source of sepsis. | Urine on admission. | Blood-urea mg. per 100 c.cm. | Urea-concentration test: maximum. | Progress in hospital. |
|---|---|---|---|---|---|---|---|---|
| 1922 (6 mths.) | 1<br>K. B. | $3^{9}/_{12}$ | Frequency. Brown urine (1 year). | Parotid abscess. | Heavy cloud of alb. Blood + +. Epith. casts. | — | Border-line, 1·9 %. | Discharged with blood in urine. B.P. 70. |
| | 2<br>E. D. | 6 | Swelling of face and legs. Dark urine. | Tonsillitis. | Alb. + + +. Blood + + +. Granular casts. | — | — | Few R.B.C.'s still present on discharge. |
| 1923 | 3<br>A. P. | 9 | Brown urine following chicken-pox. | ? | Blood +. Trace of alb. No casts. | — | Fair. 2·1 %. | Blood increased while in hospital and then cleared up. |
| | 4<br>C. A. | 6 | Discharging ear; headache; sore-throat; and bloody urine 3 weeks. | Tonsillitis. Otitis media. | Alb. + Sev. casts. R.B.C.'s +. Streptococci found. | — | — | Tonsillectomy followed by disappearance of blood from urine. |
| | 5<br>E. G. | 2 | Brown urine; puffy face, frequency; thirst. | Tonsillitis. Teeth bad. | Trace alb. Numerous R.B.C.'s. Epith. casts. | 38 | Normal. 2·9 %. | Four teeth extracted. Blood disappeared. |
| | 6<br>J. M. | $6^{6}/_{12}$ | "Thick" urine; puffy face; vomiting | Tonsillitis. | Alb. +. Blood + +. | 43 | Normal. 3·2 %. | Blood and alb. disappeared. |

### *Discussion.*

In the cases set out in Table II. it will be seen that it is not uncommon for the blood to disappear rapidly from the urine after tonsillectomy—for example, as in Cases 4, 7, 12, 20, and 21—or after the extraction of carious teeth, as in Case 5. In Case 7 the development of a boil was associated with the presence of additional blood in the urine, while in Case 18 the evacuation of a parotid abscess led to a disappearance of the blood from the urine by the next day.

A brief review of certain of the more important papers dealing with this form of renal inflammation will serve as an introduction to a short discussion of its pathology. R. S. Allison,[1] in some observations on 12 cases of acute nephritis in children grouped together six whose urine contained blood and albumin in large quantities, and remarked upon the sudden appearance of the hæmaturia in certain of these cases, which he suggested might be due to infarction. In the cases with this massive hæmaturia the blood disappeared from the urine as suddenly as it had appeared. This author did not differentiate these cases further, but they were in all probability of the acute hæmorrhagic type, which we have under discussion. Hill[2] believes that the vast majority of cases of acute nephritis in children are of infectious origin, and that more cases are secondary to tonsillitis than to scarlet fever. He classifies acute nephritis in children as acute hæmorrhagic and acute exudative, and in another paper[3] states that the hæmorrhagic type is the commoner in children. He comments on the bright red colour of the urine often seen in these cases and on the presence of only a few casts. In his cases the nephritis usually made its appearance a few days after an attack of tonsillitis, the commonest exciting cause, and lasted from 4 to 12 weeks. James[4] also makes a division of acute nephritis in children into the hæmorrhagic and exudative types. Schwartz and Kohn[5] refer to the hæmorrhagic variety and also to the more commonly recognised form which they call "nephritis parenchymatosa." In this type they found a low protein content of the blood-serum with a reversal of the normal relation of serum albumin and serum globulin. Whether this occurs or not in the hæmorrhagic type does not appear to have been determined and is an interesting point. Clausen[6] divides acute nephritis into hæmorrhagic or glomerular and parenchymatous or tubular, but this would seem to group the hæmorrhagic cases with the ordinary acute glomerular nephritis which may occur as a complication of scarlet fever for example. He draws attention to the possibility of staphylococcal infection and also to the importance of infection of the paranasal sinuses as a cause of nephritis. In discussing the prognosis of acute nephritis Osman[7] considers that it is more favourable in the hæmorrhagic cases, and states that "it appears to be almost an axiom that in acute nephritis the more the blood the better the outlook both immediate and remote." Lastly, mention must be made of a rare and curious condition described by Guthrie[8] as idiopathic or congenital, hereditary and family hæmaturia, in which blood may be present in the urine over long periods and increase in quantity in paroxysmal attacks associated with slight pyrexia. At times the urine may have the appearance of "arterial blood" and the quantity of blood passed exceeds that seen in any form of nephritis. Such cases might be mistaken for examples of hæmorrhagic nephritis, but a knowledge of the family history would prevent such an error occurring.

### *Pathology.*

Since cases of hæmorrhagic nephritis seldom come to autopsy there is no certain information as to the post-mortem appearances of the kidney in this condition. Acute congestion of the kidneys is known to occur in connexion with various inflammatory lesions, especially of a local character, and at the other extreme there is a type of embolic nephritis described by Muir[9] as a "distinct type of nephritis which is not uncommon in cases of subacute endocarditis caused by streptococci, especially the *Streptococcus viridans*." In this condition "hæmaturia is not uncommon," and sections of the kidneys frequently show blood in the tubules while there is also a patchy affection of the glomeruli. The same author points out that in puerperal eclampsia as a result of toxic action on the renal epithelium it is not unusual to get a condition of multiple infarction of the kidneys associated with hæmaturia. It is conceivable, therefore, that in acute hæmorrhagic nephritis in children there is a similar condition of multiple emboli of streptococcal origin without any widespread inflammation of the kidney substance. If the infection is prolonged it is probable that the usual glomerulonephritis or catarrhal nephritis may supervene.

TABLE III.—*Mortality Rate in 87 Cases of Nephritis.*

| | Cases. | Deaths. |
|---|---|---|
| Acute parenchymatous nephritis | 23 | 6 |
| Acute hæmorrhagic nephritis | 22 | — |
| Chronic parenchymatous nephritis | 23 | 2 |
| Chronic interstitial nephritis | 19 | 10 |

### *Prognosis.*

The prognosis in acute hæmorrhagic nephritis appears to be good. Hill, in a paper already quoted, states that death due to this type of nephritis is unknown, and none of the 22 cases here described were fatal. The mortality of the 87 cases of nephritis analysed for the purpose of this paper is shown in Table III. This only refers to cases where death occurred in hospital.

We have recently followed up the 22 cases of hæmorrhagic nephritis, and carried out a re-examination of most of the earlier ones. The results of this are shown in Table IV. The period elapsed between the onset of the nephritis and the time of re-examination varied from four months to three years, and was in most cases over a year.

* Heart normal in each case.

*Progress.*—Case 1: No other illness. Urine always red. Cases 2 to 14: No return of symptoms.

Case 1 shows that on clinical evidence it is sometimes possible to be misled about the diagnosis of this disease from the other forms of nephritis. With a "poor" urea concentration (1·9), and a blood-urea of 95 mg. per 100 c.cm., it is almost certain that interstitial changes are developing in a chronic form of nephritis. Case 10 is also classified on re-examination as doubtful. On the other hand, the prognosis in acute hæmorrhagic nephritis does not appear to be quite so good with regard to complete recovery of the kidneys as some authorities assert, for in only three of the cases (2, 11, 13) was the urine quite free from albumin, while in seven others there was a trace. A trace of albumin, unaccompanied by cells or casts, is not uncommon in healthy children, and is regarded as of no importance. But is it permissible to ignore the slight albuminuria which persisted in these seven cases? Our present opinion is that it may be safely disregarded, except in those instances where it is accompanied by an abnormal quantity of leucocytes and epithelial cells in the centrifugalised deposit. The urine in six of the seven cases referred to above still contained an abnormal number of cells. The patients re-examined had all kept well and had had no return of symptoms, except in Case 1, in which the urine remained "red." Cases 3 and 7 were not seen, but were reported to be in excellent health.

### *Conclusions.*

1. Acute nephritis in children can be separated into two main types. To one of these the term acute hæmorrhagic is given; the other is the more widely known variety, variously called "parenchymatous" or "exudative." 2. Acute hæmorrhagic nephritis is comparatively common. Twenty-two cases were admitted in three years to the Great Ormond-street Hospital. 3. From a study of these 22 cases this condition has been found to possess certain definite clinical features, which enable it to be differentiated. 4. Pathologically it is probably a form of streptococcal embolism of the kidneys, originating from some definite focus of sepsis elsewhere in the body. 5. The prognosis

is much better than in the other forms of acute nephritis, and as a rule no chronic inflammation of the kidneys results.

We are greatly indebted to the physicians of the Hospital for Sick Children for permission to publish their cases in this paper, and to Dr. G. A. Harrison who undertook the biochemical examinations.

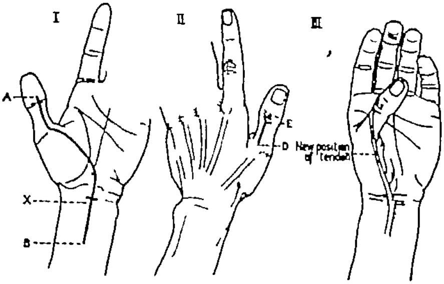
# Clinical and Laboratory Notes.

## A NEW OPERATION FOR OPPONENS PARALYSIS OF THE THUMB.

BY B. WHITCHURCH HOWELL, F.R.C.S. ENG.,
SENIOR SURGEON, QUEEN'S HOSPITAL FOR CHILDREN, LONDON; SURGEON, BROOKFIELD ORTHOPÆDIC HOSPITAL AND ROYAL SURGICAL AID SOCIETY.

THIS operation was devised by me some years ago to improve the function of a thumb in which opposition was impossible, either on account of irreparable damage to the median nerve or permanent paralysis due to anterior poliomyelitis. The operation is, in brief, a transposition of the tendon of the flexor longus pollicis performed in the following manner.



An incision, A B, is made, extending from the ball of the thumb to several inches above the transverse creases of the wrist, and the tendon isolated (Fig. I.). A second incision, E D, is then made over the dorsal aspect of the first phalanx of the thumb, well to the ulnar side (Fig. II.). The flap, A B, is then freely and carefully undercut towards the radial border of the thenar eminence. The tendon is then divided at the wrist at X and the distal end passed subcutaneously round the ulnar border of the first phalanx and out through the incision E D. Next the tendon is passed back again through this incision, passing obliquely across the tendon of the extensor longus pollicis, and comes to lie subcutaneously on the thenar eminence. The fashioning of the subcutaneous tunnel is much facilitated by the use of the old-fashioned hernia needle on a handle (Fig. III.). The incision E D is then sewn up; also incision A B with the exception of the part near X. At this stage the thumb is held in opposition with the terminal joint of the thumb extended. The distal and proximal ends of the tendon are then united at X with chromicised catgut (20-day) and the skin closed (Fig. III.). The thumb is kept in opposition by means of plaster-of-Paris, a window being cut for the wound A B. Graduated faradic stimulation of the flexor longus pollicis is commenced on the fourth day, and the stitches are removed on the tenth. Within two to three months strong sustained voluntary opposition of the thumb is effected by the transposed tendon.

The satisfactory results obtained in some eight or nine cases have encouraged me to continue to perform the operation, and to publish this short account of it. The drawings were kindly prepared for me by Mr. George F. Bird.

## A CASE OF EUCALYPTUS POISONING.

BY L. M. CHESNEY, M.B., CH.B. EDIN.,
D.P.H. DURH.

THE case of eucalyptus poisoning recorded below is interesting as compared with the case first mentioned.

During the war a patient suffering from diarrhœa was accidentally given a dose of eucalyptus and castor oil, a mixture kept for superficial wounds, burns, &c. About four hours after the dose had been taken the person who had given it came to me to ask if eucalyptus were poisonous. I looked up Martindale's "Extra Pharmacopœia" and found a reference to a case in which 1 drachm had caused violent vomiting and diarrhœa, and another in which 6 drachms had caused similar symptoms; the ages of the patients were not given. As the patient in hospital had had about 4 drachms I felt a little anxious, but no symptoms of poisoning had developed though four hours had elapsed. It seemed rather late to use a stomach-tube, so we did nothing, with the happy result that the patient was none the worse, and was quite well the next day.

### *Account of the Case.*

A short time ago I was attending a patient who had a bad cold, and was also very constipated. I ordered a dose of castor oil, to be taken early the next morning. She also told me that she had fallen and hurt her knee. I cleaned up the wound and ordered a mixture of eucalyptus and castor oil, 15 g. each, for future use; and jokingly said, as I left the house, "Don't drink the eucalyptus mixture and put the castor oil on your knee." About 7 30 the next morning I was sent for because the patient had taken the eucalyptus mixture about 6.30 A.M. She was quite well, had no sickness or other symptoms, and in view of the other case, I thought she would be all right. About 10 A.M. I was sent for again, and found her in a peculiar comatose condition. She had been sick three times, and had apparently brought up most of the oil. She had a very little pain in the right side of the abdomen, none over the epigastrium, but could hardly be roused to answer questions; her pulse was barely perceptible, and her face was ashy grey, pupils equal and reacting to light, not contracted. I gave camphor hypodermically, hot bottle for her feet, and her pulse improved. A tumbler of warm water was retained and she was not feeling sick. I was anxious about her for an hour, as her pulse continued to be very frequent and feeble, but, after two more hypodermics of camphor, it got much better, and her mental condition improved. About noon I gave a cup of hot coffee, with 2 gr. of cit. caffeine, and ordered an enema.

By 4 P.M. the patient was very much better, there had been no more sickness, the bowels had acted twice, no smell of eucalyptus in the fæces, though the patient's breath still smelt of it, the pulse was fair, 98, regular, but she felt sleepy, and, as she said, "far away." When I saw her at 9 P.M. she had quite recovered.

It seems strange, not that eucalyptus should make a person sick, or even poison him, but that anyone should give, or take, without noticing, a drug with so strong a smell. It is also remarkable that in neither case was there any intestinal irritation, a symptom which is apparently generally present in cases of eucalyptus poisoning.

Palma de Majorca, Spain.

**HASTINGS AS A HEALTH RESORT.**—The Hastings Town Council, having taken over the White Rock baths on the sea front, intends to remodel them on modern medical lines, and the medical men of the district have collectively laid recommendations before the Council. It will probably be considered necessary to make further inquiries into conditions existing in other spas, but in the m
turkish baths are being brought up to date as an

# Medical Societies.

## ROYAL SOCIETY OF MEDICINE.

### COMBINED MEETINGS OF THE SECTIONS OF OPHTHALMOLOGY AND LARYNGOLOGY.

### OPTIC NEURITIS IN ITS RELATION TO SINUSITIS.

AT a combined meeting of these Sections held on Jan. 8th, Sir ARNOLD LAWSON presiding, Dr. A. LOGAN TURNER (President of the Royal College of Surgeons, Edinburgh) introduced the subject from

*The Laryngological Standpoint.*

A conjoint meeting of the Scottish Society of Otology and Laryngology and the Scottish Ophthalmological Club decided, he said, in March, 1924, to investigate a series of cases of retrobulbar neuritis in regard to the condition of the eyes and the nasal and accessory cavities, and report on them in two years' time, and he was able to give some of the results in the Edinburgh centre so far. The ophthalmological work was done there by Dr. J. V. Paterson, Dr. A. H. Sinclair, Dr. H. M. Traquair, Dr. E. H. Cameron, and Dr. Laura M. Ligertwood, the nasal work having been contributed by Dr. J. S. Fraser and Dr. W. T. Gardiner. Dr. Turner's concern in the present discussion was to speak of 28 definite cases in their rhinological aspect. They all belonged to the retrobulbar type of optic neuritis, and the natural tendency was for the vision to recover spontaneously. This was the end-result in most of the cases examined. Some operators, he said, showed an excess of zeal in interfering with the nose and sinuses in these cases, under the belief that "latent sinusitis" was the cause of many of them. In the cases under review there was an almost complete absence of any subjective nasal symptom. In two a slight unilateral nasal obstruction was found to be due to a septal deflection, while in none of the cases did rhinoscopic examination reveal the signs which the rhinologist regarded as evidence of suppurative sinus disease. In 13 of the cases the nasal accessory sinuses were normal. In seven there was a high septal deflection to the side of the affected eye, while two showed some cloudiness of the sphenoidal sinus in the skiagram. In five cases a high septal deflection was associated with œdema of the middle turbinal on the same side. In three of the patients the nose was not examined.

Dr. Turner concluded with a general summary of the facts gleaned. In none of the 25 cases nasally examined was there clinical evidence of suppurative sinus disease, and in the six cases in which posterior sinuses were opened no pus or secretion was found. In these six the cavities were healthy in three, the remainder showing slight catarrhal changes and some evidence of congestion of the mucosa. In two of the cases a septal operation was carried out. In all the cases the vision returned to normal, or nearly normal. In three of the patients septic teeth were a possible causal factor, and after they had been extracted vision was restored. Dr. Turner said that in estimating the effect on the vision of surgical interference with the sinus cavities, due regard must be had to the fact that in these cases the tendency was towards spontaneous cure, and the operation might synchronise with the time of commencing natural resolution. A further collective investigation on the subject was needed.

*The Ophthalmological Standpoint.*

Mr. M. S. MAYOU presented the ophthalmological aspect. He said that the forms of optic neuritis which were associated with nasal disease were of two main groups having very different clinical and pathological characteristics. The first were those of papillœdema due to distension of the optic nerve sheath with fluid, causing venous obstruction by pressure on the central retinal vein as it entered the globe. There was then a slow steady failure of vision, with very marked swelling of the nerve head, often resulting in choked disc. The second group were those of retrobulbar neuritis, or, as he preferred to call the condition, interstitial neuritis; and in this condition there was an inflammatory patch, or patches, into the trabeculæ of the optic nerve, causing direct pressure on the nerve-fibres and interference with their function. The only cause of the disease of which there existed positive evidence was disseminated sclerosis, but a further cause might be infection conveyed by the blood stream from such a focus as a suppurating sinus in the nose. All the physical signs of retrobulbar neuritis could be caused by pressure on the nerve exerted by a tumour, fracture of the sphenoid, or inflammatory swelling in the vicinity of the optic foramen without the nerve substance being involved.

With regard to the relationship of nasal sinus trouble to optic neuritis, papillœdema might result from a subacute meningitis following a suppurative sphenoidal sinus opening beneath the dura, or a spreading necrosis of cranial bones as a sequel of disease of nasal bones or of operating on the nose. Rarely it might follow thrombosis of the cavernous sinus. The papillœdematous type of optic neuritis in association with meningeal infection and intracranial abscess was generally admitted; it was in the relation of the retrobulbar type to nasal disease that the meeting was particularly interested. This type of neuritis had a strong tendency to recover, whether treatment was given or not. Perhaps more light might be thrown on the association of the two diseases if a methodical examination of the fields of vision were made in a series of cases of sphenoidal sinus disease. F. C. Wallis examined 45 cases of sinus disease and found general contraction in all, central scotoma five times, optic neuritis in three cases. Mr. Mayou had had a considerable number of cases of retrobulbar neuritis examined by rhinologists, but they had never yet found one in which the sphenoidal sinus was infected. But in three of his cases the antrum was full of pus, and in one the ethmoid was infected; all four recovered after those areas were dealt with. He did not doubt the association of the two diseases, but considered that it occurred only rarely.

*Discussion.*

Mr. E. D. D. DAVIS gave the results of a study of the notes of 76 cases of retrobulbar neuritis which had been sent to him for examination of the nose in order to determine the cause of the eye condition. These patients were kept under observation for long periods and were followed up. In the 76, nasal disease could be excluded in 30, in 14 there was disseminated sclerosis, in nine syphilis, in seven the teeth were septic, and in only seven was there manifest sinus suppuration. The definite diagnosis of disseminated sclerosis was very difficult, as retrobulbar neuritis was often the first sign of the disease, and might be the only one for many years. The lapse of time and the aid of the neurologist, however, settled the problem. The neuritis was unilateral in nine, bilateral in five. Mr. Davis discussed the anatomical relations of the sphenoid and posterior ethmoid cells to the optic nerve, and said that optic neuritis arising from inflammation of the nasal sinuses could be produced in the following ways: direct extension through continuity of structure, thrombosis of venous sinuses or vessels, acute nasal catarrh, toxæmia, or bacteriæmia. Of the cases which had nasal sinus suppuration, operation in three produced a dramatically rapid improvement in the sight; in the other two optic atrophy prevented such a result. Suppuration of the antrum of nasal origin was practically always accompanied by the involvement of other sinuses such as the frontal and ethmoidal. But when antral suppuration arose from the teeth this cavity alone was involved, and retrobulbar neuritis had never been recorded in the numerous dental cases which he had had under care. A careful study of charts of fields of vision of nasal cases did not show such definite characteristics as to be relied on as aids to diagnosis. Optic neuritis arising from septic venous thrombosis was rare, and in these cases the acuteness of the illness overshadowed the symptoms of blindness. He had not seen retrobulbar neuritis occurring in the course of acute nasal catarrh. If retrobulbar neuritis in a case was increasing and every other cause for the condition had been eliminated, or there was any suspicion of sinus disease, it was justifiable to remove the middle turbinal and explore the ethmoidal and sphenoidal cells; the operative risk in skilled hands was negligible.

Mr. R. FOSTER MOORE spoke, from the ophthalmological standpoint, on cases of retrobulbar neuritis, to which group he felt sure some of Mr. Davis's cases did not properly belong. The following were the outstanding characteristics of the disease: rapid loss of central vision, some pain on globe movement, or when it was pressed back, an optic disc only slightly abnormal, a pupil which contracted to light but could not maintain that contraction, and a marked tendency to recovery. It occurred mostly between the ages of 20 and 40. Infection of the paranasal sinuses was one of the rarest causes of retrobulbar neuritis. In order to facilitate the most complete examination of the cases he always admitted them as in-patients, so that all specialists concerned could do their part. He believed that in course of time a considerable proportion of Mr. Davis's 30 cases in which the cause was not ascertained would develop disseminated sclerosis. Apart from the spread of a suppurative process from surrounding structures which had caused orbital abscess or thrombosis of vessels, he had never seen a case of retrobulbar neuritis which he regarded as due to paranasal disease.

Sir STCLAIR THOMSON said he had had but few cases of the kind now being discussed, but sometimes a small number of cases carefully studied in the way Mr. Davis had shown were better pointers than large collections. A typical case of his own was that of a lady blind in one eye who was shown just before the meeting by Mr. R. A. Greeves. She had had no symptoms pointing to sinus disease, but he opened the sphenoid and she improved somewhat. Later he opened the posterior ethmoidal cells, which were the seat of cystic degeneration. Further improvement followed this, and the patient was now quite well. Of two others one recovered equally well after operation on sinuses, but the other still remained blind.

Mr. E. TREACHER COLLINS said the first case mentioned by Sir StClair Thomson had marked papillitis, but could not be classed as retrobulbar neuritis. Following the operations on the sinuses there could be no doubt about the improvement, both in the vision, the subsidence of the swelling, and the disappearance of the retinal exudation. He had not seen a case in which retrobulbar neuritis could be attributed to sinus disease.

Mr. F. A. WILLIAMSON-NOBLE commented on the fact that all cases of retrobulbar neuritis had an optic foramen smaller than normal, suggesting that one explanation of the condition might be pressure on the nerve. In some intractable cases it might be possible to reach the foramen by the subperiosteal route and enlarge it.

Dr. P. WATSON-WILLIAMS (Bristol) said that though many cases of the condition under discussion showed a tendency to recover, a considerable number proceeded to optic atrophy. Hence no stone should be left unturned to save a patient from that catastrophe. Each case should have a careful ophthalmological examination before operation was undertaken. It seemed to be the cases in which there was an absence of marked evidence of suppuration that were more likely to have toxæmic conditions. Recently he published in THE LANCET, 1925, ii., 858, two cases showing how sinus suppuration could be overlooked. The ethmoidal cells were so often involved that they seemed to lend themselves specially to lymphatic absorption involving the optic nerve sheath.

Dr. J. A. GIBB (Maidstone) spoke of five definite cases of retrobulbar neuritis in which the ethmoidal cells were infected, and in which operation on those cells resulted in complete recovery. In those patients the optic neuritis had been in existence some weeks. In another case of double optic neuritis and retinitis the urine was loaded with albumin. It cleared up and sight was restored. In a further case syphilis was suspected, and opening the sphenoid gave no visual improvement; but thorough opening of the anterior ethmoidal cells and burring of the maxillary antrum improved the vision from 6/60 to 6/12.

Mr. D. LEIGHTON DAVIES (Cardiff) said that in his experience visible changes in the optic nerve in cases of nasal sinus disease were relatively uncommon; neither was retrobulbar neuritis of the clinical type common. In most chronic cases he found that the visual fields showed definite changes, either a peripheral or a central enlargement of the blind spot, or various forms of scotoma. The most common changes were those involving contraction of the periphery of the fields. It was concentric, and concerned white as well as colour. In severe cases the fields tended to become progressively smaller until the sinuses had been opened and drained. As these cases were always bilateral the suggestion was that the condition was toxæmic.

Mr. H. M. TRAQUAIR (Edinburgh) said he had never seen a case of retrobulbar neuritis which could be traced to nasal sinus disease, except in cases in which the nasal sinus was obviously infected. There was a tendency towards some vagueness in the diagnosis of this disease, to assume that any kind of visual defect which was characterised by central scotoma and no visible macular change or nerve change to account for the scotoma, was due to an actual inflammatory condition of the optic nerve. It was necessary, he said, carefully to dissociate pressure conditions from inflammatory conditions. It was important to study the whole patient before deciding that he was suffering from retrobulbar neuritis in the sense of an inflammatory condition of the optic nerve. He and his colleagues had found that cases of optic atrophy due to retrobulbar neuritis were quite uncommon. When the disease was bilateral there was a greater tendency to recovery than when it was unilateral, and this applied specially to older persons. And he did not think any particular changes in the fields of vision could be fixed upon as peculiar to retrobulbar neuritis following on sinus disease, but general investigation of the patient might help such a classification. When the disc was normal and central vision good, and there was no orientation difficulty, contraction of visual fields should be ascribed to organic disease of the optic nerve only very cautiously.

Dr. JOBSON HORNE said that the nasal conditions and the ocular conditions which were under discussion might be quite independent of one another. Several cases had been known in which blindness followed treatment of sphenoidal sinus disease. Many cases cleared up completely after simple nasal treatment, resection of the turbinal body and the blood-letting incidental to it. He agreed with what had been said by Dr. Turner and Mr. Moore.

Mr. GRAY CLEGG (Manchester) remarked that in no case of retrobulbar neuritis had he felt satisfied that it had been due to disease of the posterior ethmoidal or the sphenoidal sinus.

Mr. A. L. WHITEHEAD (Leeds) referred to the opportunities he had had of doing both nasal and eye work, and said that in only two of his cases of optic neuritis and papillœdema, with retinal changes, could any connexion be established with sinus suppuration, and in both those the latter was very gross. Opening up of these cells was followed by some improvement of vision, limited, however, by atrophic changes in the retina. Many of the cases recorded at this meeting might equally have been due to toxic infection which had spread via the blood or lymphatics.

Before the discussion Mr. R. AFFLECK GREEVES showed a patient, a middle-aged woman, who had retrobulbar neuritis which remained practically unchanged for six months. Then Sir StClair Thomson explored the sphenoidal sinus, and this was followed by an improvement in the vision.

A relapse, however, occurred, and therefore the ethmoids were explored and drained. Following this the pupil became normal in size, though it had no light reaction, and vision became 6/5. Bacteriological examination of the material revealed the influenza bacillus in pure culture. There had never been any cycloplegia.—Sir **StClair Thomson**, who saw the case from the beginning, related the history, stating that the patient definitely attributed her improvement to the second operation. The ethmoid showed cystic degeneration with pus.

## COMBINED SECTIONS OF MEDICINE AND THERAPEUTICS.

### Treatment of Pulmonary Tuberculosis with Sanocrysin.

A combined meeting of these Sections was held on Jan. 12th, Dr. **George Graham**, President of the Section of Therapeutics, occupying the chair, when Prof. T. R. **Elliott** opened a discussion on this subject by reading the paper which appears on p. 126.

Prof. **Lyle Cummins** spoke of 25 cases which had been treated by Prof. Elliott and himself, or were still under treatment, but paid special attention to the six cases he put under this treatment six months or longer ago, on account of the interest borne by their subsequent history. In the four cases in which the result seemed very favourable and decided improvement followed the treatment there had been a relapse. It was some time before the remedy caused an improvement in the lesions sufficient to show on the skiagram. In the first of the patients there was a fall in the body-weight during treatment, but subsequently there was an increase week by week. When she left the sanatorium after six weeks—before she was advised to—she reached 11 st., a greater weight than she had ever before achieved. But she returned to unfavourable home conditions and had a relapse, and last April returned to the sanatorium where she still remained. He intended to give her a fresh course of sanocrysin. He showed skiagrams and charts on the screen of a series of cases, the former making evident the degree of cavitation present, and the latter the temperature and weight variations. He had also treated with sanocrysin a very severe case of pneumonia, with high pyrexia. It did no good, but on the other hand no trace of harm could be found as a result of its use. It was stopped because rashes and albuminuria coincided with its use. This patient died three months after the new substance was stopped. In the favourable cases of pulmonary tuberculosis the improvement following this treatment could scarcely be denied; it was very definite and rapid. Still, all had relapsed, from the standpoint of renewing positive sputum. A second course stopped the sputum and bacilli were no longer found. He thought that in order to get results it was necessary to give a rapid course. Whether sanocrysin killed the tubercle bacilli in the body or not, it certainly led to their destruction. It did not sterilise in the doses now given in a fairly advanced case.

Prof. F. R. **Fraser** spoke of the 15 cases of tuberculosis which had been treated by Dr. Harris and himself. He said that at first they used the dosages which were recommended by the Scandinavian workers, but found it advisable to depart from that scheme. The earliest case was that of a hospital porter, aged 30, who had had hæmatemesis eight years before. When seen he had tubercle bacilli in his sputum and signs of the disease were evident in his lungs, while he also had clubbing of the fingers. The first dose was ⅓ g., and this did not produce any reaction. Three days later 1 g. was given and shortly after that he had nausea and vomiting, and on the second day after the injection the temperature began to rise, and there was a great increase in the sputum. On the fourth day after injection the temperature rose to 104° F. and a "measly" eruption appeared and later spread all over the body continuing until the tenth day. Albumin appeared in the urine when the treatment began, and on the fifth day after the second injection it increased greatly, and the man was very ill; he was eating nothing, he vomited, and complained of a strong metallic taste in his mouth. There was also a thick fur over the tongue, fauces, and soft palate. On the eleventh day after the injection he seemed to have recovered from these effects, but during the treatment he had lost 10¼ lb. On the day following he was given another dose of 1 g., and this was followed by even more reaction; so great was the collapse that he was treated by serum. This febrile reaction lasted a week, and he had not sufficiently recovered for further treatment until the twenty-third day after the injection, and he had now lost 23 lb. The next dose caused a short sharp reaction, during which he again showed collapse and had to have further serum. Subsequent doses gave no febrile reaction, but he always had anorexia, increased albuminuria, and the metallic taste in the mouth. At the end of the course of injections the physical signs were but little altered, except that there were now no râles, even on coughing, and no tubercle bacilli were detectable in his sputum. Skiagrams showed a clearing of the shadows at the right apex, and the appearance of a cavity there which had not been seen before. Shortly after he went to Frimley Sanatorium the râles returned, and tubercle bacilli were again found in the sputum. He had now been again working six months as a hospital porter, and did not seem any worse for his experiences with the treatment It was decided by the speaker and his colleagues that such severe reactions must be avoided in future, as they were not likely to be compensated by any beneficial effect of the treatment. Probably the undesirable results were due to heavy metallic poisoning. Dosage was now very slowly graduated, and the treatment was stopped as soon as a single dose of 1 g. had been reached. The effects of the serum were so disappointing that they decided not to produce sufficient reaction to require its use. He quoted a series of much more favourable cases in which this precaution was adopted; commencing with a dose of ¼ g., and as there was no reaction, ¾ g. The latter was followed by a slight reaction, therefore the next dose was ⅓ g. This patient had no marked loss of weight and no severe reaction. No succeeding dose was given until five or seven days after the effects of the previous one had passed off. Finally, he said there seemed to be clear evidence that sanocrysin had some action so that recent exudative lesions in the lung were cleared more rapidly than by any other form of treatment.

Dr. J. **Tattersall** referred to ten cases which he had treated with the remedy, four of them being still under treatment. His general run of results were distinctly favourable, but most of the cases definitely lost weight while under treatment.

Dr. **George Marshall** made some general remarks on the treatment following on his visit to Denmark, where he saw 200 cases under treatment. In that country there were now only one or two physicians who were using the large doses. The preparation was especially dangerous to the patient who had had the disease only a short time; he did not seem able to resist the reaction, probably because he had not produced the antitoxin to neutralise the toxins set free by the injection. He had arrived at the conclusion that the serum did not prevent bad results. He detailed a few results of the treatment in his own experience, mostly favourable.

Dr. F. R. G. **Heaf** detailed his results of the treatment in 24 cases in Warwickshire sanatorium, starting with a dose of only 0·1 g. of sanocrysin, and going on to 0·25, 0·5, and 0·75 before reaching a 1 g. dose. His results were favourable.

Sir **Almroth Wright** spoke of the disappointment which sanocrysin had been. It had been claimed as a drug which directly attacked the tubercle bacillus and killed it. If that were so it could be given in a big dose, short of killing the patient, and it would kill off most of the microbes. It was brought in as a method of chemotherapy, but it was not that. It attacked the organs of the body also. In his laboratory experiments were made among the workers by putting the tubercle bacillus into their own blood. The tubercle bacillus grew enormously in the normal person's blood, so that after a week there were very large colonies. It was easy to take the blood and add sanocrysin to it. One drachm in the blood had no effect on the tubercle bacillus. A dose of 1 in 250 could be given and yet the tubercle bacillus would go on growing inside the blood. He concluded that the preparation had no effect on tubercle bacilli, and that he regarded as a calamity. Poisoning certainly occurred from it because it attacked many tissues of the body, but he was prepared to believe that these reactions exerted a favourable influence in some cases; indeed, many other reactions did the same. Experiments done with rabbits showed that the material had no effect on the tubercle bacilli. In the patients spoken of by others the bacilli when not found in the sputum might have been carried to other parts of the body because they subsequently returned to the sputum.

Prof. Elliott and Prof. Cummins briefly replied.

## SECTION OF SURGERY.

A meeting of this Section was held on Jan. 6th, Sir Lenthal Cheatle, the President, occupying the chair, when Prof. C. A. Pannett opened a discussion on the

*Surgical Treatment of Duodenal Ulcer*

by reading the paper which appeared in our last issue.

The President said that if he were in the unit working under Prof. Pannett he would ask that he might do post-mortem examinations on hundreds of cases, whatever might have been the cause of death, in the hope of discovering very early duodenal and very early gastric ulcers, as that was a form of spadework which really needed to be done. With regard to the possible cause of these ulcers, in the examination of animals which had died and happened to have been suffering from duodenal or gastric ulcer, the very small early ulcers were found to contain spirochætes; whether they caused the ulcers was a matter which required to be worked out. Only very early investigation would supply the solution. At present he was satisfied in these cases with the operation of posterior gastro-jejunostomy, and believed the main factor in the success of it was to make the stomach opening 4 in. in length; 2½ in. was too small, for it allowed half the stomach contents to pass through the duodenum and half into the jejunum. With the larger incision very little passed into the duodenum.

Mr. A. J. Walton did not agree that only a small proportion of cases of duodenal ulcer required surgical treatment; no proof had yet been advanced that medical means had cured or definitely improved actual ulcer in that situation. And certainly one should never wait for hæmorrhage to occur before undertaking surgical measures, especially as quite a number of these cases died from hæmorrhage, which was more fatal in duodenal than in gastric ulcer. Sometimes the surgeon was not called in until hæmorrhage had occurred, but an attempt at a diagnosis should be made as early as possible. He believed high acidity had much to do with causing these ulcers. He had never yet seen a case of pure jejunal ulcer. Post-operative ulcers started at the junction and were essentially gastro-jejunal. In 1063 operations on stomach and duodenum, pyloric and duodenal ulcers numbered 437. In order to get a correct impression as to results it was essential to have a "follow-up" department and continually to review the cases. He had had such a department at the hospital since 1917 and that enabled him to be very definite when he spoke of results. Among patients traced for two years or more after operation the cases he had lost amounted to about 3 per cent. He agreed that simple gastro-enterostomy might be followed by hæmorrhage or by perforation at the seat of the ulcer, and because of that he had advocated that this operation should be accompanied by bedding or suturing of the ulcer.

With regard to mortality, he agreed that the usual conditions in a draughty hospital ward were the worst possible for these cases. Some hospitals had post-operative wards, and if these were to become general he was satisfied there would be an improvement in the mortality statistics of these cases as a whole. He considered that the mortality after gastro-enterostomy should not exceed 2 per cent. He had found that 90 per cent. of the cases after operation were really cured, and by that he meant that a man who worked hard had no reminder that he had a stomach and could eat anything after having gone six months without medical treatment. The big danger was that of gastro-jejunal ulcer. In his 137 pyloric and duodenal ulcers, gastro-jejunal ulcer occurred in 2·5 per cent. He thought faulty technique was a considerable factor in mortality figures. The operation suggested by Prof. Pannett should not be done generally, because of the risks in less expert hands. And partial gastrectomy did not protect a patient from gastro-jejunal ulcer. The aim of the surgeon should be to practise the least interference which would cure the patient.

Mr. H. W. Carson said it must be agreed that the diagnosis of duodenal ulcer was not easy, as there was often so little to go on, and even the services of the highly skilled radiologist did not give such a high percentage of positive results as Americans claimed. Also, chemical means had largely failed. Thus one had to rely more and more on the history given by the patient, often a fallacious matter. This made it the more necessary to receive with caution Prof. Pannett's statement that the majority of duodenal ulcers were cured by medical means, a statement which he did not accept, though he agreed that duodenal *symptoms* could be medically cured. The opinion seemed to be increasing that these ulcers had a septic origin, and when the abdomen was open there should be a search for any septic focus within the accessible area. He asked whether it was the general view that the intermissions observed in cases of duodenal ulcer meant that the ulcer was then soundly healed and that the renewal of symptoms indicated that it had broken down again; also, was it right to do, in the quiescent period, a prophylactic operation to prevent the inevitable symptoms at a later date? Gastro-jejunostomy was not attended by a high mortality, and the great risk was not in the abdomen but from chest complications afterwards, and for that the surgeon must take his share of the blame. This operation, however, did not keep permanently lowered the degree of stomach acidity, and in those cases of a high activity there was reason to expect unsatisfactory sequelæ. If the latter were going to appear he thought they would do so within six months of the operation, and if not then the patient was safe. If there was trouble years after the operation he believed it could not be debited to the operation. He did not think an operation of the severity of duodenectomy was justifiable at present, certainly not for general performance.

Mr. C. H. Fagge said it was excellent that the surgeon should be able to declare that he had not seen this or that, and one of the best ways to find out what he had seen and had not seen was to deal with the primary lesion in the way Prof. Pannett advised. He (the speaker) had never seen a jejunal ulcer, but he had met with only three or four gastro-jejunal ulcers, in all of which an unabsorbable suture must have had something to do with the ulcer. All the duodenal ulcers he had seen were in the pylorus. Balfour showed by statistics that pyloric ulcers occurred in only 1 per cent. of cases, as against Prof. Pannett's 12 per cent. The majority of supposedly pyloric ulcers were really duodenal. He was not satisfied with gastro-jejunostomy in the treatment of duodenal ulcer, because an appreciable number of his cases bled after that operation. He was pleased to see William Mayo, 12 years ago, excising duodenal ulcers, and he (Mr. Fagge) had since then excised every duodenal ulcer in his cases in which he thought that was possible; the majority of them were on the anterior surface of the duodenum. In the last few years he had done excision by a horizontal incision of the duodenal ulcer, if on the anterior surface, and then suturing up the hole in a vertical direction; though it was yet early to speak of results, he believed they were as good as his former figures. Some duodenal ulcers were so small that they could easily be overlooked.

Mr. T. P. DUNHILL said he believed duodenal ulcer could be accurately diagnosed before operation, and he did not open an abdomen unless an ulcer was revealed by the skiagram. He did not think all these ulcers were of similar kind; they differed in complications and evolution, and some had fairly large hæmorrhages with long intervals between, while others were more or less continually bleeding. Most of the patients were made enormously better by the operation of gastro-jejunostomy, though he did not think the proportion was as high as Mr. Walton's 90 per cent. Medical men who had been so treated constituted an efficient "follow-up" department, and in them there was evidence afterwards of greater sensitiveness to dietetic indiscretions and to excessive use of tobacco. He had never thought it wise to attempt resection of the duodenum for large callous ulcer in which there was much penetration of the wall; the patient's life must always be the prime consideration. He kept as his sheet-anchor for these cases gastro-jejunostomy.

Mr. C. A. JOLL also thought the skilled radiologist could give a high proportion of positive diagnostic results in these cases; out of 50 cases he recently looked through, 49 had been correctly recognised in this way, the remaining one being doubtful. Most of the cases, by the time they came to the surgeon, had already had medical treatment, and he did not think there was any evidence that duodenal ulcer had ever been cured by medical means. He believed a straightforward, well-conducted gastro-enterostomy would cure 90 per cent. of the cases; when there was serious bleeding a direct attack must be made on the ulcer by duodenectomy.

Mr. C. MAX PAGE said that in the last five years he had operated on many "second-hand" stomachs, and as a result he had formed a poor opinion of the efficacy of gastro-enterostomy; he believed that the operation, as generally carried out in England, could give a high percentage of bad results. Duodenectomy he did not regard as such a very dangerous operation, and he advocated an intelligent trial of methods other than gastro-enterostomy, remembering that high mortality was always the price of a surgical departure before good results justified its general adoption.

Mr. V. ZACHARY COPE did not feel satisfied with the dogmatic statements as to the failure to cure these ulcers by medical means. Even when the abdomen was opened one could not always tell whether a duodenal ulcer was present; inspection of only the anterior wall was not conclusive. He was sure acute ulcers sometimes healed spontaneously.

Prof. PANNETT, in reply, said he did not believe in a focal infection as a cause of these ulcers. He had cultivated streptococci obtained from the wall of a sterilised ulcer and injected them into a rabbit without any result; he had done the same with *B. coli*, streptococci, staphylococci, and diphtheroids from gastric ulcer, and again with no result on the animal when injected intravenously. He therefore hoped people would not have their antra opened or tonsils enucleated before having duodenal ulcer directly treated. He agreed it was exceptional for symptoms to occur more than six months after operation. His attitude was that which had been mentioned by Mr. Max Page; he felt that if a promising new method in surgery was to be abstained from because it appeared to be dangerous, surgery would stagnate. When he did duodenectomy—which had produced, with him, 7 per cent. mortality—he did not see the small intestine, and that was the reason patients went through the operation with very little shock or other bad after-effects. Resection was the right treatment for bleeding ulcers. Hæmorrhage from gastric and duodenal ulcers was always of the secondary type.

## PATHOLOGICAL SOCIETY.

A MEETING of the Pathological Society of Great Britain and Ireland was held at the Lister Institute on Jan. 8th and 9th, Profs. C. J. MARTIN and J. C. G. LEDINGHAM presiding.

C. Da Fano (London) described the histological changes in the brains of rabbits observed during the transmission of epidemic encephalitis and contrasted them with those produced by the herpetic virus; "minute bodies," sometimes double, were abundant. With J. R. Perdrau he also dealt with some unusually severe changes in the cerebral cortex of rabbits in herpetic meningo-encephalitis, and compared them with some of the lesions of chronic encephalitis lethargica.—J. G. Greenfield (London) demonstrated the fourth English case of Schilder's encephalitis periaxialis diffusa with its characteristic perivascular degeneration of myelin sheaths and later of axis cylinders with subsequent neuroglial overgrowth.—G. S. Williamson and I. H. Pearse (London) pointed out that in fishes the thyroid is often slung in a lymph sac, and described the variations in the abundance and granulations of the mast-cell-like components of the reticulo-endothelium of the gland associated with variations in diet and functional activity.—J. S. Dunn (Manchester) found that oxalates and uranium salts caused necrosis of the suprarenal cortex which was apparently made good by active regeneration of the surrounding cells; similar changes might be produced by particles such as starch grains. He also proposed that the histological facts suggested that the outer parts of the cortex are continually proliferating and the cells being pushed into the medulla where they disintegrate.—F. W. Lamb (Birmingham) described a case of malignant change occurring in the muscular elements of an adenomyoma of the recto-genital space; the lungs were diffusely infiltrated and the alveolar walls greatly thickened by tumour tissue which appeared to be the cause of an intense polycythæmia which developed. He also demonstrated two other curious tumours.—W. G. Barnard (London), from a study of 17 cases of malignant disease about the root of the lung, concluded that the oat-celled tumours generally regarded as lymphosarcomata are really carcinomata of alveolar epithelium.—D. F. Cappell (Glasgow) described a case of malignant chordoma of the cervical spine in a man of 59.—L. Gheorghiu (Brussels and London) had made a long series of experiments on the possibility of adapting mouse tumours to grow in rats. By inoculating new-born rats he had been able to carry on a mouse tumour for 20 passages covering a year, and the tumour progressively grew better and was absorbed later. It, however, remained a mouse tumour, for it was always absorbed in the end and would not grow at all in adult rats.—R. Muir (Glasgow) restated his position with regard to the nature of Paget's disease which he looks upon as a change of rather low malignancy of the deeper layers of the epidermis, beginning usually in the ducts and spreading thence to the nipple and more rarely to the secreting acini.—H. W. Crowe (Harrogate) had obtained micrococci from the tissues of cases of rheumatoid arthritis but not from normal tissues.—T. S. P. Strangeways and R. G. Canti (Cambridge) showed and discussed the finer changes in the nuclei and mitochondria of living cells observed in vitro under dark-ground illumination.—R. P. Smith and D. W. Patterson (Newcastle) described a case of thrombo-angeitis of the lower leg in a syphilitic.—S. McDonald, T. Oliver, and W. E. Cooke (Newcastle) showed some strange bodies found in the fibrosed lung of an asbestos worker who died with chronic pneumonia and tuberculous cavitation; they resembled minute insects or larvæ and were presumed to be the remains of asbestos fibres fretted by long exposure to the body fluids.—E. G. D. Murray, M. B. R. Swann, and R. A. Webb (Cambridge) gave an account of a rabbit epidemic associated with poor spring feeding caused by a diphtheroid bacillus, scattered focal necrosis in the tissues, and a remarkable excess of large hyaline leucocytes which were specifically phagocytic towards the organism.—A. F. B. Shaw (Newcastle) pointed out that accurate leucocyte counts could be obtained only if there was a free flow of blood through the part (rabbit's or human ear); any vaso-constriction led to results which were very irregular and always much too high.—E. H. Lepper and C. J. Martin (London) showed a quick and simple method of determining the hydrogen-ion concentration of a drop of capillary blood.—J. O. W. Barratt (London) discussed the fundamentals of a hydrolytic dissociation curve.—N. D. Ball (London) dealt with the serological differentiation of species and varieties of higher animals. The brown rat cannot be distinguished from the black rat by precipitation tests; the mouse is clearly distinct from either; the white and black-and-white domestic varieties of the brown rat cannot be separated from the wild form; four fanciers' varieties of pigeons could not be distinguished from one another.—H. R. Dean and R. A. Webb (Cambridge), in a study of the precipitin reaction, found that the rate at which the precipitate appears depends on the balance between antigen and antibody; the mixture which precipitates quickest is not the one which precipitates most.—H. J. B. Fry (London) gave an account of his further work on the serum diagnosis of malignant disease; a saline- and acetone-insoluble, alcohol-soluble cholesterinised extract from carcinoma of breast gave flocculation with the sera of 75 per cent. of cases of carcinoma and sarcoma, and negative results with 75 per cent. of cases without malignant tumours.—E. M. Dunlop (Glasgow) described the fixation of the complement of normal guinea-pig serum by the typhoid bacillus in the absence of antibody, a property which could be removed by treating the serum with bacilli or coal-dust.—A. N. Goyle, J. A. Arkwright, and I. Balteanu (London) discussed the serological and immune relationships of the rough and smooth, motile and non-motile variants of typhoid and Gaertner, paratyphoid A and cholera bacilli respectively, and pointed out how the data could be interpreted in terms of antigenic structure.—P. Bruce White (Bristol) dealt in the same way with the whole Salmonella group, and indicated how those species which were specific parasites show signs of the usual parasitic degeneration either in a simplification and stabilisation of their antigenic constitution or by loss of flagella.—G. S. Wilson (Manchester) could find no clear connexion between age and virulence for mice in the Aertrycke bacillus.—W. J. Tulloch (Dundee) had promising results in guinea pigs with a protective vaccine made by killing tubercle bacilli in olive oil.—C. H. Browning and H. Gulbransen (Glasgow) said that mice were not so resistant to tuberculosis as was often supposed, and described a massive broncho-pneumonia developing in about half the animals infected by feeding and in some 10 per cent. of those inoculated.—H. D. Wright (London) found that a second injection of pneumococci disappeared from the blood much more quickly than a first injection; this acceleration began to appear in a few hours after the first dose, reached its maximum in about three days, and then persisted for months; it was independent of antibodies.—T. Dalling (London) described the titration of *B. welchii* toxin and antitoxin and the successful protection of young lambs against a fatal diarrhœa by vaccinating their mothers. With C. C. Okell he also gave an account of the successful protection of dogs against "yellows" by vaccination with a killed emulsion of *Leptospira* made from the liver of infected guinea-pigs.—A. Piney (London) dealt with the nutritive requirements in nitrogen of colon and typhoid bacilli.—N. Raw (London) showed cultures of human and bovine tubercle which had become quite non-pathogenic after cultivation for 19 years.—C. C. Okell and G. I. Steed (London) described the anæmia and jaundice following the intravenous injection of horse serum into mice, due to the natural agglutinin which is present.—Exhibits were also made by F. W. Lamb (Birmingham), Hodgkin's disease of cervical glands; W. G. Barnard (London), stenosis of aorta; A. E. Boycott (London), green alga parasitic in the snail *Limnæa*; H. M. Perry (London), skin tumours of xeroderma pigmentosum; R. D. Passey and H. E. Harding (London), transplantable cutaneous mouse melanoma; M. J. Stewart and A. L. Taylor (Leeds), carcinoid tumours of appendix and Meckel's diverticulum; T. Lumsden (London), immunity to tumours; S. P. Bedson and H. Maitland (London), foot-and-mouth disease lesions in guinea-pigs; H. M. Woodcock (London), *Glugea* of angler fish; H. Chick, H. Roscoe, and V. Korenchevsky (London), prevention of rickets in rats by pasture-fed butter; J. Kirkpatrick, colour microphotographs.

## NEWCASTLE UPON-TYNE AND NORTHERN COUNTIES MEDICAL SOCIETY.

AT a meeting of this Society, held at Newcastle on Jan. 7th, at which Dr. NEIL MACLAY presided, Dr. L. M. WEEKS read a paper on

### *Pre-Maternity Work in General Practice.*

Discussing the problem of educating patients to seek advice as early as possible, and if possible before the third month of pregnancy, Dr. Weeks said that prejudices against examination were easily overcome, and that invariably women returned of their own accord in a second pregnancy if adequate care and interest had been shown in the pre-maternity consultations for the first pregnancy. At the first consultation in the early months a pelvic examination was not necessary unless there was a history of frequent miscarriages in a woman with a negative Wassermann, or in cases of slight hæmorrhage suggesting ectopic gestation. Rather should the first consultation be devoted to a routine inquiry into previous illnesses, previous menstrual history, history of previous pregnancies, and present symptoms, followed by a clinical examination of the heart, lungs, and urine. This was the time to give the woman advice in general rules of health during the rest of pregnancy, with warning to report such symptoms as would suggest pyelitis, miscarriage, placenta prævia, or eclampsia. Teeth with the tendency to decay should receive special attention.

After this there should be monthly examinations of the urine up to the eighth month, when a further examination should be carried out to determine the position of the fœtus by abdominal palpation. A breech or transverse presentation should then be corrected to a vertex by external rotation and the correction should be maintained by pads and binder. An occipito-posterior should also be corrected. In these cases a further examination should be carried out two weeks later and special attention should be paid to the recognition of that type of case in which the head was high above the pelvic brim at this stage, freely movable and not descending. Some interference with the lower uterine segment should be suspected in these, such as contracted pelvis, false promontory, fibroids, placenta prævia. In these circumstances a pelvic examination should be done and the true conjugate measured. The important deformity termed funnel-shaped pelvis should also be looked for. The great value of these pre-maternity examinations was that the type of case likely to require Cæsarean section or other special treatment could be recognised before labour began.

Mr. H. HARVEY EVERS gave a short address on *Albuminuria during Pregnancy*, and a discussion followed in which Dr. W. HERBERTSON spoke with enthusiasm of the help he had received by the routine antenatal examination of 150 of his cases in a general practice among industrial patients. Any scepticism or suspicion on the part of the patient was quickly swept away, and he had no hesitation in saying that the adoption of a definite pre-maternity scheme in general practice was one of the greatest advances in preventive medicine.

The rest of the meeting was devoted to a demonstration of clinical cases.

# NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

At a meeting of this Society held at Liverpool on Dec. 18th last, Dr. John E. Gemmell, the President, delivered an address on the

## *Progress of Obstetrics and Gynæcology during the Last Forty Years.*

He said that before 1885, when he graduated at Edinburgh, the only pelvic operations he had seen were perineorrhaphy, trachelorrhaphy, the cauterisation of hæmorrhoids, and one ovariotomy, which was performed by Thomas Keith with much ceremony in an isolated room at the Royal Infirmary. Gynæcology was then a small subject, chiefly limited to out-patient and consulting-room work, not free from the taint of quackery, and sometimes a target for the shafts of the satirist. Dr. Gemmell gave an interesting description of the changes wrought since then, describing, for instance, how the work of many surgeons led up to the modern extensive abdominal hysterectomy for carcinoma of the cervix associated with Wertheim's name. The science and art of gynæcology, he said, now stood upon a firm basis, and it should not be forgotten that the pioneer work of the ovariotomists had paved the way for successful surgery in the upper abdomen.

## *The Ganglia of the Cervix Uteri.*

Dr. Arthur Gemmell (Liverpool) said that the study of the nerve-supply to the uterus was receiving renewed attention, but the function of this nerve-supply had been more fully recorded than its anatomy, and nothing had been written on the pathological changes associated with gynæcological diseases. Most observers were now satisfied that the uterus was supplied mainly by the sympathetic proper (the white rami from the lower dorsal and first and second lumbar nerves), via the inferior mesenteric ganglion and hypogastric plexus to the ganglia of the cervix uteri and thence to the uterus itself. All authors agreed that there were cervical ganglia, and some postulated others in addition. They gave only scanty information as to the site of the cervical ganglia, but placed them at about the level of the internal os. Dr. Gemmell said that his work had been done on whole specimens removed by Wertheim's hysterectomy. No definite attempt has been made to investigate the presence or absence of intramural ganglia, but in none of the sections examined were any such seen. Dissection of the ganglia, even with the aid of dissecting binoculars, was found to be impossible, and so a block of tissue centred on the uterine artery was cut out of the parametrium. This included a piece of uterine wall, and the whole of it was examined by serial sections. Latterly this block had been divided into four and the postero-inferior portion of it cut serially. The ganglia were always found by this method if they were present, and it appeared that they lay internal to the ureter, posterior to the uterine artery, and at a little distance from the uterine wall. Sections were studied from six patients who died from various diseases not involving the genital organs, and in all these cases ganglia were found. The ages of these patients varied from 7 months to 65 years.

Dr. Fletcher Shaw (Manchester) asked whether Dr. Gemmell had examined the parametrium behind the uterus. He had been very much struck by the excessive amount of shock shown by patients when he had enucleated tumours or growths from this region and had often thought that this part must be especially well supplied from the sympathetic system.

Dr. Leith Murray (Liverpool) remarked that an extension of malignancy from the cervix had been observed in these ganglia and along the related nerves. Dr. Gemmell's interesting research might be important from that point of view.

Dr. Gemmell, in reply, said that he thought that there were some variations in the positions of these ganglia, as in some specimens he had been unable to find them anywhere in the parametrium available. There was the possibility that interference with the ganglia might account for the shock following Wertheim's operation. The utero-sacral ligaments and posterior portion of the parametrium had not been examined as it was thought that there was more chance of finding sympathetic elements along the vessels.

## *Locked Twins.*

Prof. Miles Phillips (Sheffield) reported a case of impactions of twins, one of the rarest forms of obstructed labour. The patient was a primigravida and twins had been recognised by her doctor at an antenatal examination a week before she came into labour. The fœtal heart-sounds were easily heard at both sides of the abdomen. Labour began at 7.30 a.m., the pains being weak and irregular; but by 10.30 a.m. on the following day the cervix was fully dilated. The contractions were then strong, no progress was made, and Prof. Phillips saw the patient at 12.30 p.m. The uterus was not in tonic contraction, but was contracting so frequently that it was impossible to palpate the fœtal parts. No fœtal heart-sounds could be heard. The patient was anæsthetised and placed in the lithotomy position. A head was visible, low in the pelvis, unduly soft, with a large caput and the skin peeling. By passing a hand alongside the head a rounded mass—apparently a second head—could be felt at the pelvic brim impinging on the neck of the presenting child. It was impossible to push the second head out of the pelvis, and a tentative pull with forceps on the lower head failed to move it. The first head was obviously becoming macerated, and so, after perforation to afford the necessary room, the neck was cut through with curved scissors, the head withdrawn, and the trunk pushed aside. The second head, soft and pulpy, then entered the pelvic cavity and was easily extracted with forceps. This child was also dead. The children were males, weighing 5½ and 5 lb. respectively. No liquor amnii was seen and nobody could state when the bag of membranes ruptured. The placenta weighed only 1 lb.; otherwise it appeared healthy, both macro- and microscopically. It might well be that a relative placental insufficiency had caused the death of the fœtuses, either just before, or during, the not very protracted labour, as it was thought that at least one fœtal heart had been heard on the day before delivery. The single chorion showed a central opening about 4 in. in diameter. The amniotic membrane was in two portions, each attached to the root of the umbilical cord, and, over a limited area, to one another. At some time during the pregnancy this had been perforated. At numerous other cases of twin labour which Prof. Phillips had seen, two distinct sacs had existed, the second presenting and being ruptured after the delivery of the first child. Such an arrangement appeared to render collision of the two fœtuses extremely unlikely. On the other hand, the loss of all the liquor amnii from two communicating sacs would conduce to this very rare complication.

Miss Frances Ivens (Liverpool) mentioned that she had had a case of locked twins some years ago. The patient was a primigravida. After considerable delay in the second stage, the first twin was felt presenting by the vertex, and the second lying transversely with its neck very much elongated and stretched across the neck of the first. The transverse twin was dislodged and pushed upwards by the hand in the uterus. The first was then delivered by forceps, and the second presented as a vertex and was also delivered by forceps.

Dr. Daniel Dougal (Manchester) referred to a case admitted to St. Mary's Hospital, Manchester, as a "failed forceps" case. Under anæsthesia a hand passed into the vagina found that the advance of the first child was obstructed by the head of the second one. Delivery was easily effected by pushing the second out of the way. The first child was dead;

this was probably due to injuries during previous attempts to deliver with forceps. Both children were small, and this might account for the second head being able to pass into the pelvic brim and so cause obstruction.

Dr. Gordon FitzGerald (Manchester) had seen a case in which the first fœtus presented by the breech and the second was a vertex presentation. Number one was born as far as the umbilicus when the patient was admitted to hospital. Investigation showed that the chin of number one was locked on the chin of number two. Liberation of the head of number two was impossible, and, accordingly, as number one was dead, it was decapitated. The delivery of number two was then easily completed. There was, however, some difficulty in extracting the head of the first fœtus.

Prof. H. Briggs (Liverpool) remarked that in the absence of the actual fœtuses he gratefully accepted Prof. Miles Phillips's clinical description as exact and complete. In the laboratory of practical obstetrics Prof. Briggs had utterly failed in experimentally locking twins, and he was unprepared to accept reports of fœtal incidents or complications within the pelvic cavity or at the brim of the pelvis in the second stage of labour, unless the whole of the hand of the obstetrician had been previously placed within the pelvic cavity.

### *Exhibition of Cases.*

At the end of this discussion Dr. D. Dougal reported two cases of vaginal myoma.

Mr. W. W. King (Sheffield) described a case of chorion-epithelioma in which a metastatic growth was present at the vulva during the course of an intra-uterine pregnancy, and Dr. FitzGerald exhibited a specimen showing adenomyoma of the recto-genital space and sarcoma of the ovary.

## EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of this Society held on Dec. 9th last, Dr. R. W. Johnstone, the President, occupied the chair, and Prof. Ranken Lyle (Newcastle) read a paper on the ethical and scientific aspects of the

### *Prevention, Conservation, and Destruction of Intra-uterine Life.*

Prof. Lyle began by saying that the whole trend of medical thought about the conservation of intra-uterine life had been slowly changing during the last 25 years and that the child's life was now considered nearly as important as the mother's. The intrinsic duty of the medical profession was to preserve and prolong life—that is, the life of the ovum—from the period of gestation to the death of the individual. At one time patients used always to be sterilised after Cæsarean section, but now Prof. Lyle considered sterilisation to be an insult to surgery; it prevented a woman carrying out her mission in life. He himself had only once sterilised a patient after Cæsarean section—25 years ago—and had performed Cæsarean section as often as seven times on one patient. Induction of abortion for medical reasons ought to be prohibited. Nearly every case of hyperemesis gravidarum could be cured by hygienic treatment, suggestion, and psychotherapy, and toxic cases which required abortion to be induced were very rare. In tuberculous patients pregnancy should be allowed to go on without interruption, as also in those with heart disease—at any rate until the later months when pressure was being caused by the growing uterus, when the question of induction of labour or Cæsarean section must be considered. Chorea gravidarum very rarely nowadays warranted induction of abortion. Cæsarean section had taken the place of craniotomy on the living child, which was never necessary, and by this the maternal as well as the fœtal mortality would be greatly improved. Cæsarean section was also taking the place of bipolar version as the treatment for placenta prævia, and the operation had considerably lowered the fœtal death-rate without increasing the maternal mortality. Even in cases of prolapse of the cord, especially in a primipara, Cæsarean section was advocated to save the child's life.

Antenatal care had been instrumental in revolutionising abnormal obstetrics and preventing the majority of cases of difficult labour. By this means eclampsia had been checked to a large extent, with a great saving of both mothers' and children's lives. Abnormal presentations could now be rectified before the confinement, and breech, face, and transverse presentations could be converted to normal vertex positions. This allowed many children to be born alive who would have died had the case not been under antenatal supervision. By antenatal examination contracted pelves could be diagnosed early and the necessary treatment decided upon before labour was begun. This was very different from seeing the case advanced in labour at a time when any treatment was likely to be dangerous to both mother and child.

### *Discussion.*

Dr. Haig Ferguson said that Prof. Lyle aimed at high ideals, but sometimes these were unattainable. He did not agree that Cæsarean section cases should never be sterilised; he thought that if a woman had been through the ordeal of three Cæsarean sections she had a right to be sterilised if she so desired. Where the induction of abortion was contemplated the interests of the mother should be considered before those of the child if they clashed, and in his opinion the operation should be permitted in some cases of tuberculosis, insanity, diabetes, recent heart disease, and hyperemesis gravidarum. Craniotomy was a repugnant operation, but in domestic practice it was sometimes necessary.

Dr. W. Fordyce agreed with Dr. Ferguson that the maternal life was the first consideration. He thought that the cases of hyperemesis gravidarum in Newcastle could not be quite so severe as they were in Edinburgh, where induction of abortion was in some cases the only treatment possible to save the mother's life. He was sure, also, that some cases of chorea gravidarum warranted obstetric interference. Dr. Fordyce agreed with Prof. Lyle that Cæsarean section was desirable in cases of central placenta prævia in primiparæ.

Prof. B. P. Watson said that when a certain treatment had been found for hyperemesis and other conditions, no fœtal life would have to be sacrificed; but at present there were cases that defied all treatment, and in these abortion had to be induced to save the mother's life. With regard to sterilisation after Cæsarean section, the patient's view must be taken into consideration, and this was especially desirable when the operation was being performed for a decompensated heart lesion. There were some cases which warranted craniotomy; for example, a primipara badly lacerated with a raised temperature and the fœtal head jammed in the pelvis.

Dr. James Young was surprised at Prof. Lyle's assurance that 80–90 per cent. of children could be saved by Cæsarean section in cases of placenta prævia, and thought it a strong argument in favour of such an operation. He agreed with Prof. Watson on the value of craniotomy in the definitely septic case.

Dr. Farquhar Murray (Newcastle) considered that craniotomy was never justifiable on the living child, but on a dead child it might be performed when the head was low down and easily accessible.

Dr. Keppie Paterson thought that craniotomy on the living child was still a necessary evil.

The President said that antenatal care alone could help obstetricians to reach the high ideals of Prof. Lyle. At present, he thought, there were still some cases which required induction of abortion and craniotomy. Sterilisation by deliberate operation was hardly ever justified, but after several Cæsarean sections it was often indicated in the best interest of patients.

Prof. Lyle, in reply, said that in 1900 one Cæsarean section had been regarded as an indication for sterilisation. At the present meeting three was the number suggested. Ten years later the number would still be increasing, and soon seven would be reached. Cases of hyperemesis should be treated early, before jaundice came on; up to this year he had never induced abortion in such cases, and he had only seen one patient die. Cæsarean section, he was convinced, would give better results than craniotomy even in septic cases.

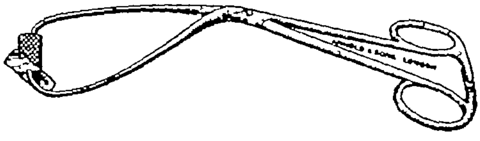
*Post-mortem Cæsarean Section.*

Dr. G. W. YULE read a communication on a case of post-mortem Cæsarean section in a twin pregnancy, with survival of one child. A primigravida, aged 25, an albuminuric, eight and a half months pregnant, who had been about 12 hours in labour, was anæsthetised in preparation for the application of low forceps to terminate the labour. Some degree of hydramnios was suspected, but no signs of either maternal or fœtal distress were noted. Upon a catheter being passed she suddenly collapsed and was apparently dead; all attempts at resuscitation, including tracheotomy, failed. Fully five minutes after death had occurred Cæsarean section was performed and a child was extracted. This child failed to respond to treatment, but when the surgeon was preparing to close the abdomen, fully ten minutes after the patient's death, a second child was discovered. It was at once removed, responded to prolonged treatment, and left hospital quite well ten days later.

# New Inventions.

## NEW CLAMP FOR USE AFTER TONSILLECTOMY.

THE instrument here illustrated has been designed primarily for use in enucleation of tonsils by the blunt guillotine. The square-ended blade is fitted with a small piece of rubber sponge (1⅛ in. by ¼ in. by ¾ in. approximately; a piece of the common "Sorbo" ball can easily be cut to the required shape, slit to receive the blade and sewn on), and a small gauze bag made with a purse-string thread at the neck is slipped over the sponge at the time of operation and the thread pulled tight. The other blade is covered with a piece of rubber tubing. The instrument is applied immediately after the enucleation of the tonsil—the sponge-covered blade to the tonsil bed and the other blade behind the angle of the jaw. A clear field for the removal of the second tonsil is then left. When both instruments are applied bleeding is prevented. Two instruments—right and left—are required for each operation. In emergency in case of reactionary hæmorrhage this instrument may also be useful.



I am indebted to Messrs. Arnold and Sons (incorporating John Bell and Croyden, Ltd.), from whom the instrument can be obtained, for help in carrying out the experimental work in the making of it.

C. D. AGASSIZ, M.D. Aberd., M.R.C.P. Lond.

REVISION OF THE PHARMACOPŒIA.—The Pharmaceutical Society of Great Britain has accepted the invitation of the Pharmacopœia Committee of the General Medical Council to send two delegates to a conference on general questions connected with the revision of the Pharmacopœia to be held in London on Feb. 23rd at 11 A.M. The other bodies that have been invited to send delegates are the Ministry of Health, the Royal Society, the Royal Society of Medicine, the Medical Research Council, the British Medical Association, the Physiological Society, the Chemical Society, and the Linnean Society.

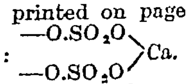
# Reviews and Notices of Books.

## THE CHEMICAL ANALYSIS OF FOODS.

A Practical Treatise on the Examination of Foodstuffs and the Detection of Adulterants. By HENRY EDWARD COX, M.Sc., Ph.D. Lond., F.I.C., Public Analyst for the Metropolitan Borough of Hampstead. London: J. and A. Churchill. 1926. With 38 illustrations. Pp. 323. 18*s.*

THE significance of pure food for the welfare of the community needs no emphasis to our readers. The busy practitioner may have little time to spare for the study of the technical details of food analysis, but will be glad to have accessible a readable account of the main outlines of the methods employed in the examination of foodstuffs and of the nature of the adulterants commonly met with. This volume, though addressed primarily to chemists, is written from the point of view of the requirements of public health and of the Sale of Food and Drugs Act rather than that of the worker in a particular branch of the food industry, and is not too technical to be appreciated by those without special experience

The first chapter deals with analysis of sugars, treacle, honey, jam, and marmalade, and opens with a brief survey of the characters of the commoner sugars and the methods employed in their identification. The emphasis upon the melting points of the pure sugars would seem unduly insistent in view of the relative unimportance of this constant compared with the crystalline form and melting points of the respective osazones, which receive but scant mention, while the characteristic phenyl hydrazone of mannose is entirely ignored. Among the methods given for the estimation of sugars it is refreshing to find the iodometric method of Willstätter and Schudel; on the other hand, no mention is made of Bertrand's convenient and reliable method for estimating sugars. That the author is quick to avail himself of new methods is shown by the fact of his having adopted the process published only a few months ago by King (*Analyst*, 1925, l., 371) for the estimation of agar-agar in jam; this method is based upon the recognition within recent years by Haas (*Biochem. Jour.*, 1921, xv., 469) of the occurrence of ethereal sulphates in the mucilaginous extracts of a number of sea-weeds such as Irish moss. In this connexion we observe that the formula printed on page 41 is incomplete and should read:



$$\left.\begin{matrix}-O.SO_2O\\-O.SO_2O\end{matrix}\right\rangle Ca.$$

The second chapter, which is devoted to starches, cereals, flour, bread, custard, and blanc-mange powders, contains drawings of starch grains derived from 24 different sources; attention is drawn to the recent work of Woodman (*Jour Agric. Sci.*, 1922, xlvi., 231), offering a chemical interpretation of the meaning of "strength" in flour. The approved methods of carrying out the Marsh, Berzelius, and Gutzeit methods for estimating arsenic are also described. The third chapter contains some interesting data concerning the composition of eggs and egg oil which are not usually to be found in books on food analysis. In the fourth chapter some account of the nature and methods of estimating pectin are given in connexion with the analysis of fruits; this is a subject which has come to the fore within recent years, and its inclusion in this volume is welcome. The estimation of the total acidity of fruit is facilitated by the use of a simple type of hydrogen electrode here described for the electrometric estimation of hydrogen-ion concentration. The fifth and sixth chapters are devoted to the analysis of tea, coffee, cocoa, and spices. In the seventh chapter the method described for estimating sulphur dioxide in wine is of importance in view of the recent Public Health Regulations which permit the use of this preservative in alcoholic wines. The examination of flesh foods, sausages, and potted meats is dealt with in the eighth chapter; attention is drawn to the occurrence of arsenic in fresh fish, and figures are given for the amounts of this element shown by the author's analyses to be present in a number of well-known and commonly consumed fish. The ninth and tenth chapters are concerned with the analysis of milk and milk products and of butter and cheese, and the last chapter is devoted to fats and oils. In an appendix the Public Health (Preservatives, &c., in Food) Regulations, 1925, which are to come into force on Jan. 1st, 1927, are well summarised; the main provisions of the two schedules are given in small compass.

The whole book is thoroughly practical, and describes in an intelligible manner methods of food analysis which can be trusted to give reliable results.

---

### SURGICAL METHODS.

*Methods in Surgery.* By GLOVER H. COPHER, M.D., Instructor in Surgery, Washington University School of Medicine. London: Henry Kimpton. 1925. Pp. 282. 11s.

THIS book consists of a description of the routine methods employed in the surgical divisions of Barnes Hospital, St. Louis Children's Hospital, and Washington University Dispensary, including outlines for case-history taking, and instruction upon pre-operative and post-operative care of patients and diets. It is for the guidance of the house officers and students working in the hospitals enumerated above, and while much of the material is of a very special nature and of interest only to these individuals, some of the suggestions and instructions may appeal to a wider field and prove of use, especially to those who have to devise schemes of work for the surgical sections of other hospitals. The book is thoroughly up to date and includes, for example, full information for the carrying out of cholecystography by Graham's method.

---

### ABDOMINAL AND PELVIC SURGERY.

For Practitioners. By RUTHERFORD MORISON, M.A., D.C.L., LL.D., M.B., F.R.C.S., Consulting Surgeon, Royal Infirmary, Newcastle-on-Tyne; Emeritus Professor of Surgery, Durham University. London: Oxford University Press. 1925. Pp. 212. 8s. 6d.

ONE of the most difficult problems the practitioner has to face is the differentiation of serious from minor complaints of sudden onset. The lives of most sufferers from acute abdominal disease lie in the hands of the family doctor. Unless he recognises its early signs the efforts of the most skilled surgeon are of no avail. To help him in detecting such serious conditions promptly Mr. Morison has written this book. The task could scarcely have been done more effectively. The outlook is designedly simple and the author insists only on essential things.

The book is a welcome addition to the series of small handbooks emanating from the Oxford University Press, which will be read through with interest and kept for reference.

---

### RECENT ADVANCES IN PHYSIOLOGY.

By C. LOVATT EVANS, D.Sc. Lond., M.R.C.S., L.R.C.P., F.R.S. London: J. and A. Churchill. 1925. Pp. 301. 10s. 6d.

SCIENTIFIC investigation of biological problems usually proceeds to-day along one of two general routes. In the first place a *tissue—blood*, muscle, or nerve—may be removed from its normal physiological surroundings and studied in its reactions to varying conditions of physical and chemical environment. An analysis of these reactions is attempted in terms of physics and chemistry. Clearly this field becomes the playground of those scientists whose familiarity with the character of inorganic reactions interests and justifies them in applying this knowledge to comparatively simple biological, or comparatively complicated physico-chemical, systems. The basal mechanism is the investigator's bait. In the second place the reactions of a tissue or organ, retained as far as possible within its normal physiological environment, may be studied in its relation to the activity of other organs. Here we are dealing with a far more complicated state of affairs, and in the absence of a knowledge of the reactive mechanisms of all the tissues involved, we have to confine ourselves largely to the description without essaying the interpretation of the phenomena studied. An attempt is made to study the interdependence of various organs and so to correlate their activities the one with the other. This is the field of the experimental physiologist.

Prof. Lovatt Evans in this book has condensed into a comparatively small space a description of the progress made by physiologists during the last few years along the lines indicated above. The book is divided into 11 chapters, and it is interesting to note that half of them are devoted to blood and the circulation, showing in no uncertain manner the great importance which must inevitably be attached to the study both of such a fundamental problem as the "internal medium of the body" and of the mechanism and regulation of its supply to the tissues. Following an excellent account of the capillary circulation a chapter is devoted to the mechanism of tissue oxidation, from which the reader is naturally led to an account of the mechanism of muscular contraction in both its chemical and physical aspects. The application to the physiology of muscular exercise in man of the results of researches on the chemistry and physics of contraction forms the title of another chapter, in which a remarkably clear account is given of recent work from A. V. Hill's laboratory. A description of recent work on the active principles of the thyroid, pituitary, and pancreas fills a further chapter, and the book is concluded by two fascinating accounts of the recent work of Magnus on the mechanism of postural reflexes and the functions of the labyrinth and of that of Pavlov and his school on conditioned reflexes. The book is intended for "the more seriously-minded students reading for an intermediate examination for a medical degree" and also "for the guidance of students preparing for honours examinations." It will doubtless gain the wide circulation it deserves, not only amongst those who are studying for the higher examinations but also amongst those who are actively engaged in biological research. There are a few misprints which can be made good in a future edition.

We congratulate the author on the attractive and instructive manner in which he has written the book. Its production must have entailed a large expenditure of time in sifting the diluted literature of contemporary physiology and of thought in its condensation into such a small compass.

### THERAPEUTICS.

*The Art of Medical Treatment.* With Reference both to the Patient and to his Friends. By FRANCIS W. PALFREY, M.D., Visiting Physician, Boston City Hospital; Instructor in Medicine, Harvard University. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 403. 21s.

ONE striking feature of this book is noted in the subtitle, "With Reference both to the Patient and to his Friends." The patient's friends do not, of course, require treatment, but they do require explanations, and the proper handling of anxious and, it may be, interfering relatives is an integral part of the treatment of most cases of illness. This subject is here touched on in a way which is, so far as we know, unique. The practitioner, in his earlier days, finds that the medicine given to his patient is but a part of his treatment, that nursing arrangements are equally important, and that the management of the friends is often the most harassing part of the case. [illegible] Palfrey even goes so far as to note the management, in the above sense, of the local health and [illegible] With these various ideas in view, each [illegible] dealt with under definite headings, some of [illegible] worth naming, if only for their [illegible]

*Thoughts* introduces the subject, gives broad lines of treatment, and notes matters demanding emphasis; *Placing* gives items of posture and environment; *Supportive* denotes the means of supporting the patient against the disease; *Information* tells us what can be said, subject to considerations already discussed, when the facts are to be told; *Preventive* includes precautions and reports. Apart from these special features the book itself is just a straightforward exposition of treatment in general practice. If it does not go deeply into out-of-the-way methods, it at least lays down the ordinary means of treatment clearly, and should prove a good friend.

*Favourite Prescriptions.* By Espine Ward, M.D., West African Medical Staff. London: J. and A. Churchill. 1926. Pp. 96. 5*s.*

Every medical man in practice collects prescriptions consciously or unconsciously. The wise generally have some small interleaved book in which they write them down, and it is not a bad plan to make a hospital pharmacopœia the basis of such a collection. That which Dr. Ward has published is a sound one, and is offered in interleaved form.

*The Book of Prescriptions.* With Notes on the Pharmacology and Therapeutics of the more important Drugs. Eleventh edition. By E. W. Lucas, C.B.E., late Member of the British Pharmacopœia Reference Committee; and H. B. Stevens, O.B.E., late Lecturer on Pharmacy and Food and Drugs in the South-Western Polytechnic Institute. London: J. and A. Churchill. 1926. Pp. 382. 10*s.* 6*d.*

A book in its seventieth year—the first edition, by Henry Beasley, was issued in 1856—and its eleventh edition is certainly worthy of note. Perhaps pharmacology and prescriptions conduce more to the long life of a book than, let us say, surgery. The frequent repetition of official pharmacopœias maintains a standard of freshness, whereas in surgery, even though a book is kept up to date for a certain time in its facts, its framework tends to get out of date and out of repair. We can congratulate the writers, who are two eminent pharmaceutical chemists, on the age and the freshness of this work. It treats of medicine from the pharmacological and pharmaceutical side rather than the purely medical one. Recent introductions receive full notice and prescriptions are given illustrating the use of many of the drugs. This is a handy little book of reference.

Colloidal Gold.

*Kolloidforschung in Einzeldarstellungen.* Vol. II. Edited by R. Zsigmondy. *Das kolloide Gold in Biologie and Medizin.* By Ernst Joël. Leipzig: Akademische Verlagsgesellschaft. 1925. Pp. 115. M.6.

This little book contains a complete account of the uses of colloidal solutions of gold in biological and medical work. It commences with a very brief account of Zsigmondy's early observations upon the precipitability of colloidal gold solutions by electrolytes and with the protective action of various other colloids. The gold members of various proteins and fluids are then dealt with, after which Lange's reaction with the cerebro-spinal fluid is discussed. The clinical application of this reaction in the diagnosis of syphilitic lesions of the nervous system is reviewed and particular stress is laid on the recent work of Eskuchen. The use of colloidal gold solutions in the study of proteins is next dealt with, whilst the volume concludes with a very short chapter on the gold numbers of blood serum, urine, and gastric juice. A fine series of references is included at the end, though the author has overlooked some rather important English work; for instance, a paper by J. Cruickshank is not referred to at all, whilst the work of J. Mellanby and T. Anwyl-Davies receives too brief mention.

## JOURNALS.

British Journal of Ophthalmology, November and December, 1925.—In the November number the chief place is given to the discussion on miners' nystagmus at the Royal Society of Medicine last February, which was chiefly remarkable for the variety of views represented. It seems to be generally admitted that oscillation of the eyeballs in dim light can be explained by the physiological properties of the fovea centralis, and the fact that as large a proportion as one-quarter of all miners working underground in the dark do develop latent nystagmus—i.e., can be shown by suitable tests to have oscillating eyeballs—strongly suggests that this view is correct. As to whether improvement in lighting is a sufficient remedy there appears, however, still to be a remarkable divergence of opinion. The orthodox view that lighting will prevent nystagmus is here represented by T. Lister Llewellyn and J. S. Haldane. Others, including M. Culpin and the late C. F. Harford, look upon miners' nystagmus as a neurosis analogous to shell shock or "railway spine." F. Robson maintains his thesis that the gaseous emanations from certain sorts of coal are mainly responsible for the condition, while Prof. E. L. Collis and G. H. Pooley blame the compensation laws. In their view these encourage a large number of men with defective health or defective will to become pensioners on the industry because they can actually obtain more money by this means than by any other open to them.——In the December number H. Neame is partially responsible for two papers. The first, of pathological interest, describes a case of endothelioma of the optic nerve; the second, of clinical importance, is on glaucoma secondary to choroidal sarcoma. Of 402 cases excised on account of glaucoma, approximately 10 per cent. were found on pathological examination to contain a choroidal sarcoma; 4 per cent. were blind glaucomatous eyes in which there appears from the clinical notes to have been no suspicion of the existence of a new growth. This establishes the urgent importance of enucleation in the case of blind glaucomatous eyes, in which ophthalmoscopic examination is not possible.

Medical Women's International Journal. Vol. I., No. 2. November, 1925.—The second number of the organ of the Medical Women's International Association, which is to be published twice a year, contains a foreword by Lady Barrett, President of the Association, setting out some of the ways in which medical women of all countries united in an association may hope to serve the world.—Reports follow from seven of the twenty national corresponding secretaries, notably from Dr. Helga Meisen (Denmark), Dr. Hermine Heusler-Edenhuizen (Germany), Miss Louisa Martindale (Great Britain), Dr. Curjel Wilson (India), Dr. Szczawinska (Poland), Dr. Marie Feyler (Switzerland), and Dr. Kate Mead (U.S.A.). These give some account of the work being carried on by medical women, collectively or individually, in the respective countries.—Reports of an international congress on child welfare, held in Geneva in August, 1925, are contributed by Dr. Cornaz-Wyler and by Dr. Elizabeth Sloan Chesser.—Dr. Alice Hamilton describes the fourth international medical congress of industrial accidents and diseases held in Amsterdam in September, while Dr. Agnes Savill deals with the International Congress of Radiology which took place in London last June.—Original articles include an abstract of a paper read by Dr. Clelia Lollini at a congress of medical women held in Milan in 1924, on women in connexion with the struggle against tuberculosis.—Dr. Alice M. Pennell contributes an article entitled A Medical Woman in India.—Dr. Esther Loring Richards writes on the Psychiatric Aspects of Child Welfare, and Lady Berry, M.D., on International Work and the M.W.I.A.—The first of a series of articles dealing with Post-graduate Research Work being carried out by medical women in various countries and a few reviews conclude the number.

THE LANCET.

*LONDON: SATURDAY, JANUARY 16, 1926.*

## THE COUNTY PATHOLOGICAL SERVICE.

THE offer by a county council to provide a comprehensive pathological service for the county is no new idea; and to those who have not grasped exactly either what the proper employment of a pathological laboratory is or the position of those who have to render the necessary expert service, the idea appears sensible and progressive, and has received advocacy. But for some time it has been obvious that, unless such a service, in so far as it is comprehensive in what it is prepared to do, recognises that a proportion of its benefits ought not to be offered gratuitously in all circumstances and to all comers, the working out of the idea may be mischievous, while the highly important section of the medical profession devoted to pathological work may be placed at an extreme disadvantage. In the report of the Medical Research Council for the year 1923–24 the position of the sciences of pathology and bacteriology, on which so much of the current work of medicine depends, was briefly reviewed and was not considered altogether satisfactory, mainly because the departments of pathology and bacteriology at many universities were built up on a basis of commercial work, and in conditions likely to disturb research and to monopolise the time of a professor and his staff, to the detriment of better things. Let us remember that valuable criticism in considering the circumstances that may arise out of hasty and ill-devised schemes for the provision by counties of a pathological service. It is not denied that many universities were aided very substantially in the equipment of teaching from the commercial value of the work done by the professors, and the procedure can be held justified, as an interim course, both because the universities were carrying out duties of public utility and were earning money which was spent upon the provision of facilities for research, but no one wants to see such sources of revenue confirmed as an ideal of attainment.

Now we see the hope expressed that, by development of the competency of local authorities to provide a public pathological service, the need for the trading activities of the universities will disappear. This may be so, and is a powerful reason for watchfulness lest the pursuit of bacteriology and pathology should suffer under ill-directed action by county councils, whereby the conditions under which the best qualified students of these subjects outside the universities might lose proper scope and opportunity. The whole matter has come to the fore recently under separate aspects, but all are parts of the same picture. The pathological facilities offered by the Staffordshire County Council have been considerably criticised. Here the situation has been discussed by the Council of the British Medical Association, when the position of the Association was defined by Dr. H. B. BRACKENBURY, the chairman of the Representative Body, and it was concluded by the meeting to refer the questions at issue to a special committee, with a reference to consider the policy of the Association in regard to the work of the private practitioner in pathology, and to pathological laboratories advertised by commercial firms. In both connexions it must be insisted that the private practitioner has public duties as pathologist to his hospital, and private relations with medical practitioners in his environment. We have before us a list of the tests which can be done in the laboratory of the Staffordshire County Council, which is a development of the V.D. centre for Wolverhampton, and though situated in the grounds of the county voluntary hospital is distinct from the pathological department of this hospital. From this schedule it seems that the practitioners of the county can obtain results of a comprehensive assortment of tests gratuitously, in all circumstances, and for all classes of patients. If a county can supply such inclusive and minute pathological and bacteriological assistance, and for all classes of patients, without any money passing, while commercialism may be truly said to be removed from the county authorities, and while the authorities may be relieving the universities to some extent from the activities at which the Medical Research Council has looked askance, it would seem that these desirable issues will be obtained at the expense of any medical man in the county desirous of practising as a bacteriologist and pathologist. This position, were it to become general, would not only be a serious threat to the material prospects of a highly equipped body of medical men whose numbers are increasing as the intimate relations of their special work with medicine and surgery becomes more and more obvious, but it may destroy that very quality of intimacy upon which the value of expert pathology mainly depends. If the medical activities of county councils should develop wrongly, not only will the standing of private pathologists be gravely jeopardised, but all the value which is so rightly laid upon close coöperation between the practitioner and the pathologist will disappear. Surely it is only by having pathologists available for consultation that this coöperation with private practitioners can be maintained; and surely, also, any tendency to regard a county laboratory as a slot machine for its neighbourhood, ready to engulf a bottle of urine, sputum, or what not, and to return a diagnosis and a bottle of vaccines, is a line along which scientific medicine can never progress. The pathological laboratories attached to commercial firms already are in competition with much of the work of individual practitioners, and they are able to call attention to their productions in a direct way in which private pathologists cannot follow them. This is a point upon which some of the pathologists attached to charitable institutions feel sore, and quite intelligibly, but such rivalry is without the unfair elements that exist where a county council organisation enters the lists. For the laboratory of the county council is rate-supported, and obtains its subsidy in earnest of its public health work. All the good that the county council laboratory can do in public health directions is rightly done for the public, and the rates pay; but the rate-supported service is designed for public health work, and when a county council proposes to give gratuitous assistance in the form of medical diagnosis in other directions its action cannot be justified, in relation either to the progress of science or to the proper interests of scientific workers.

The action of the Staffordshire County Council is particularly unfortunate at this juncture of time, for the report of the Royal Commission on National Health Insurance is expected to make recommendations which will hopelessly complicate the proposed procedure in Staffordshire. Common foresight would have suggested waiting to see whether the Royal

Commission will or will not recommend that under the medical benefits given to the insured there shall be provided a pathological service of experts. If this occurs, all that pathological work which lies outside the confines of public health would naturally be undertaken by individual pathologists for the most part in the laboratories provided in the voluntary hospitals. These pathologists would be the experts whom the practitioners of the district will consult for their panel patients in accordance with a statutory scale, and for their private patients in response to proper fees. The extension of medical benefits which is expected will demand a proportionate increase in the number of medical men working at pathology whose services, while partly at the disposal of the panels, should also be available for other than the insured population, and these will not be expected, or expect, to accept the advantages gratuitously. In other words, the expert pathologist, like the medical practitioner in other branches, will give of his best in response both to those who pay through the State and to those who pay individually. The natural centres for the work of these men will be the laboratories attached to the voluntary hospitals which are, on the one hand, acting as centres for the insured patients of their districts, and which, on the other hand, provide a medical staff for coöperation with the practitioners of the neighbourhood. Proper arrangements between the great commercial firms and the medical profession can be looked for safely, but the competition of county laboratories becomes a serious matter for the private pathologist when a county council, at its laboratory, proposes to do what does not come within the proper purview of a county authority.

◆

## HOUSING AND HYGIENE.

Have we turned the corner as regards the housing problem? The Minister of Health, in whom the members of the public health services have great confidence, appears optimistic; last month he stated in the House of Commons that more houses were built during 1925 than the annual average during the building boom at the beginning of the century, and that more schemes for slum clearances were submitted and confirmed in the six years 1919 to 1925 than in the 24 years before the war. All that is good hearing, but Dr. F. E. Fremantle was right when he emphasised that what was wanted now was goodwill and national endeavour. Of late years the job of building has largely passed out of the hands of the private builder into those of the local sanitary authority and of the Government. Whether this transfer is temporary and accidental, or marks a permanent tendency in the conduct of affairs, even the clerk to the London County Council has not made up his mind.[1] In any case the housing question needs to be lifted out of the ruts of trades-union politics and party dissensions, and medical men should take every opportunity of using their special knowledge for the general enlightenment. For medical men there has been sufficient evidence in the past as to the effects on health of bad housing to make comment appear superfluous, but because the doctors and the statisticians know the connexion between the prevalence of diseases in various localities and the housing accommodation in those localities —its character, the number of rooms per house, and the rest—it does not follow that the public is equally well informed. No pains should be spared to advance cogent arguments as to the relation between bad housing and bad health. The families which occupy the worst houses are generally the worst off in all other respects, and this may disguise the most fundamental of their drawbacks, which is their home.

What are the essentials of a healthy home? During the debate on Dec. 18th last in the House of Commons Sir Leslie Scott referred to the 2246 back-to-back houses of Liverpool as being unfit for anyone to live in for a week. We are hardly in a position, however, to damn all houses of the back-to-back type without particular consideration. In his report for 1924 the medical officer of health for Leeds states that, although more than two-thirds of the houses in that great city are built back to back, about half of them are of a type which does not differ appreciably in healthiness from through houses. Only two-thirds of the deaths from all causes in Leeds during 1924 occurred in these back-to-back houses—in other words, they had their proper proportion of deaths. But no health officer has any doubt that on the whole disease is more prevalent and more fatal in bad than in good houses. Exact evidence on the question is, however, singularly lacking, although we may well hope that it will be made good in the five-year survey which the Minister of Health has asked for to accompany the 1925 reports. Some indications may, however, be quoted. Dr. Stanley Banks, in his recent report for the Burgh of Motherwell and Wishaw, states that there are 13,965 inhabited houses in his burgh and that 72·3 per cent. of the population live in houses of one or two rooms. The notifications of tuberculosis, he finds, are higher in the very small houses; the 19 per cent. of the population who live in one-roomed houses contributed 35 per cent. of the notifications of tuberculosis for the period 1921 to 1924. Dr. Banks also deals with the incidence of other infectious diseases on the persons living in houses of each class during the years 1923 and 1924, and says that the attack rate of scarlet fever and diphtheria "hardly varies at all with size of house," but for pneumonia "the attack rate is considerably higher in the one-roomed and to a lesser extent in the two-roomed house." Speaking generally, it is notorious that we have had exceptionally low death-rates during all this period of bad housing. It is possible that a better educated people has to some extent been able to rise triumphant over its housing troubles. There have been signs, however, during the last year or two of a set-back to the progressive improvement of the tuberculosis death-rate. To turn to morbidity, Sir John Robertson believes the amount of rickets in such "flatted" towns as Glasgow, Munich, and Chicago to be ten times as great as in the towns where cottages predominate.[2] Dr. Austin Priestman's recent inquiry into adenoids and otorrhœa among Folkestone school-children leads him to regard overcrowding and insanitary conditions as almost the sole factors in their production.[3]

Until the 1925 reports come in from the public health service most people will be content to rest the case for better housing on the tribulations of houseless families in every part of the country and on those conditions which make the decencies of life utterly impossible. There is more than enough evidence before the public already to show that this problem is urgent and must be faced. The peculiar knowledge of doctors, however, and the fact that the public health is more the concern of the doctors than anyone else, make it necessary that they should leave no stone unturned in promoting national endeavour and in rousing the national conscience. In a letter published in our columns, a correspondent offers the kind of evidence—evidence of failure—which must be brought home to the nation, and pleads for the coöperative effort which ought to be a main contribution of the profession to the political and social life of to day.

## MALARIA AND INDUSTRY.

A HAPPY discrimination is shown by the public demand which has necessitated the re-issue, in the *Indian Journal of Medical Research* for October, 1925, of two Government publications[1] under the title "Two Malarial Surveys Connected with Industrial Projects in Certain very Highly Malarious Localities in India." Both these industrial concerns are, in fact, situated in areas where malaria is hyperendemic.

The first comprises about 10,000 acres of a wide, almost level, plain of high grass jungle interspersed with swamp, near the foothills bounding the valley of the Brahmaputra to the north. Habitations have been placed where they would interfere least with agricultural operations—namely, on trimmings of land lying along swamp and stream which breed those recognised malaria carriers *Anopheles listoni* and *A. minimus*. In the layout of the estate it was clearly not recognised that malaria might determine the commercial value of the undertaking and that the first procedure should have been a malaria survey to determine, within the area selected for cultivation, the most suitable housing site—which in this instance would have been the central plot of the estate. As a result 91 per cent. of the children had, at the time of the inquiry, palpable spleens. Owing to heavy invaliding the staff of Europeans, mechanics, and servants is constantly changing, recruitment is a difficulty, and the cost of training the new staff considerable. Regarding a remedy, and writing with personal knowledge of the subsoil drainage system which has so successfully combated malaria in the Federated Malay States, Colonel CHRISTOPHERS held this procedure to be here financially impracticable. It will, however, be recollected that Sir MALCOLM WATSON himself visited, in 1924, a large group of tea estates in Upper Assam, where *A. maculatus* and *A. minimus* are abundant, instituted a system of subsoil drainage designed to strike at their breeding-places, and expressed little doubt that malaria would soon be under control.

The other industrial venture concerns mines in the Singhbhum District of Bihar and Orissa. The mining camps lie in alluvial-bottomed valleys within the hills. Inspection was made during three weeks of the cold season. The average spleen-rate in children was 69. The basis of the inquiry, perhaps the first instance on which this has been attempted from the hygienic aspect, is a quantitative determination of the degree of infection by malaria parasites in the cutaneous blood; and the conclusions to which it leads are striking. By spreading a determined quantity of blood in a thick film upon a determined area of slide, examining this with a square-apertured ocular giving a field of determined size, and counting the parasites in 200 square fields, the number of malaria parasites in a cubic millimetre of blood was estimated. It varied, where they were detected, from 4 to 131,282; 85 per cent. of parasites came from those who had lived on the estate for two years and under. In those who had been born on the estate the similar percentage was 92. Infection in the second year of residence approximated to 100 per cent., and the average parasite value was over 12,000 per c.mm. Now the number of parasites always associated with febrile attacks of 103° F. or over seemed here to be somewhat under 5000 per c.mm. and Colonel CHRISTOPHERS calculates that, by his figures, which apply to the cold, non-malarious season, hyperendemicity is to be associated with an infection so intense that it practically amounts to a continuous attack, with over 10,000 parasites per c.mm., extending over a period of two years. This stage is designated as "acute infestation." Over the age of 2, while the proportion of children infected is as high as ever, the average number of parasites falls to 1200 per c.mm. between two and five years, and to 1000 between six and ten. This stage is designated "immune infestation." Similar figures apply to immigrant non-immune children, at least during the first two years of residence. Correlating these counts with enlarged spleens, it was found that a spleen projecting 4 to 6 cm. from the costal margin (correction being made to a sitting height of 60 cm.) was that associated with acute infestation. It is concluded that the net result of passing childhood under hyperendemic conditions is the acquirement of a form of immunity. The parasitic forms found were almost uniformly rings of 2 to 3 $\mu$ in diameter, identified tentatively as *Plasmodium tenue* Stephens, 1914. The readiness with which Colonel CHRISTOPHERS will be followed on this point will depend on the extent to which it is believed that the differences on which this form is separated from *P. falciparum* are reliable, when there is used, as is customary with malariologists, a mode of preparation which is rejected for other protozoa as giving no reliable information regarding structure. Gametocyte formation was associated with heavy infection of the cutaneous blood and with the period of acute infestation. The proportion of gametocytes to rings was 1 to 390. Of adults, 51 per cent. were found infected and the average number of parasites was 100 per c.mm. It is concluded that this peculiar relationship of low value of infection and high percentage of infected must represent immunity in the adult. In them, as in children, crescents were associated with the heavier infections.

These considerations have this practical value, that the present labour is "salted," and not in such urgent need of protection as are "non-immune" persons. Observations of the 15 species of anopheles discovered point to *A. listoni* and *A. culifaciens* as primarily implicated in infection, with *A. willmori* as an unknown element of danger. In the matter of preventing breeding there is a short length in one ravine held suitable for treatment along the lines of subsoil drainage so extensively and happily employed in the Federated Malay States. For the rest it is concluded that the most fundamental work open to the Company is the choice in the first instance of situations for lines, quarters, and bungalows that are either naturally free from liability to anophelism or can be made so with the least difficulty. If outside labour be imported from relatively non-malarious parts serious incapacity is to be expected, and the choice of suitable situations for their lines would become almost the only practicable antimalarial measure which would not be excessively costly. The fundamental error of both these large industrial concerns is, then, that they have been instituted in hyperendemic areas without any prior effort being made to determine how even minimal infection of the staff could be avoided. Their present heavy financial handicap is the direct result of their failure to obtain sound sanitary advice before launching into heavy expenditure.

# Annotations.

"Ne quid nimis."

## LONDON PORT SANITATION.

Dr. W. M. Willoughby reports to his Sanitary Committee that no case of plague, cholera, typhus, or small-pox had to be dealt with during 1924 in the Port of London; no plague-infected rat was found; the 21,783 aliens arriving were clean, healthy, and louse-free; and the food and sanitary inspections were carried out satisfactorily. In April of that year a number of foreign medical officers were shown the Port, and especially its methods for dealing with infectious disease. The most important duty of a port authority is to prevent the importation of infectious disease and unwholesome food; infection is kept out more easily now that port medical officers everywhere pool their knowledge. Bulletins telegraphed from ports abroad enable the authorities to get a clear idea of the prevalent epidemics, and incidentally render obsolete the system by which ships are still expected to bring with them a mass of papers dealing with the public health at their ports of call. The chief problem at present is plague, and the necessary destruction of rats. A ship is mentioned —obviously that referred to in the health report [1] of Cardiff Port—which was suspected and was carefully examined in London and Cardiff without any rats being found. Two cases of plague occurred on board before she reached Port Said, and when she was fumigated at Suez ten rats were killed. Forty rats were reported to have been killed in a fumigation four months previously. The infection probably occurred in South America, whence she had carried a cargo of grain. After discharging this she was loaded with coal, and the rats must have gathered themselves round the pantries; a steward's boy, whose cabin was next a pantry, got right and left femoral buboes. Dr. Willoughby, to whom so much of our knowledge of the epidemiology of plague on board ships is due, remarks that there may quite well be an outbreak of plague on board a ship even if it has only few rats, provided that they become infected and that there is no particular attraction for them in the cargo in the holds to keep them at a distance from the crew. Port health reports record not only cases of infectious disease which have been seen, but also those which occur during the voyages of the ships entering harbour. This accounts for the frequency with which small-pox and tubercle are mentioned. Of small-pox, 12 cases occurred among crews and five among passengers, but in no case did the disease spread, thanks to the immediate vaccination of contacts. Of the 66 cases of pulmonary tubercle landed in London, 16 were taken care of by the Seamen's Hospital Society, along with 30 cases of other forms of tuberculosis. Malaria caused much illness on board a ship at Bombay. Her third officer fell ill with malaria on the eighteenth day after arrival there, by which time the ship had reached Port Said on her way back, and died on the twenty-seventh day. There were no other deaths, but 8 Europeans and 16 natives of the crew were infected, and had to be sent to the care of the Seamen's Hospital Society as soon as they reached London. Bombay has lately gained an unfortunate reputation for spreading malaria, both in the Navy [2] and in the Mercantile Marine. A story is told [3] of a ship disabled at Karachi in 1924 on account of half the crew being down with malaria contracted at Bombay. But in fact the progress that has been made at Bombay in stamping out malaria is remarkable, considering the situation and social life of the city. At the present time there is a certain amount of malaria on nearly all ships trading with India, and it is constantly present amongst native crews. It cannot be expected, however, that Bombay can abolish the disease and thus protect all sailors entering the port, although the progressive reclamation going on in the harbour will in time reduce malaria. What is required is a far more generous distribution of quinine to crews visiting Eastern waters. Dengue is mentioned as often attacking ships during voyages, especially in voyages from Calcutta. 187 seamen came to notice suffering from venereal disease. In ships 14,922 rats were killed, 13,742 in dock warehouses; 64 ships were fumigated with sulphur (29 rats killed, on an average), and seven ships with hydrocyanic acid (80 rats killed, on an average). About the docks two brown rats are killed to every black (or plague-carrying) rat. It seems to be suggested that it is safer to fumigate the whole of a ship at one time; in one case the holds only were fumigated with sulphur dioxide, and no dead rats were found, but after a later fumigation 55 rats were found in the crew's quarters, where they may have found harbourage during the earlier partial fumigation.

There were 16,455 inspections of ships, and 210 were found defective; 2509 nuisances or sanitary defects in ships were reported and dealt with, the most numerous being dirt, smoke, bad lighting, leaks, defective ventilation, and improperly kept sanitary conveniences. 3000 tons of foodstuffs were condemned as unfit for human food, and 130 tons were destroyed. Actinomycosis was found in 1·5 per cent. of ox-tongues but in 5 per cent. of "ox-tongue roots," and 463 quarters of formalinised frozen beef were destroyed owing to the formalin having made the beef indigestible and so unfit for food. Cashew nuts with maggots in them were condemned, in spite of the protests of the importers, and permission to re-export was refused. Permission was also refused in the case of spinach which had been greened with copper sulphate, 5 gr. to the pound. Unboiled periwinkles were found to be spreading typhoid in the neighbourhood of Southend. The question of latrines about the docks is having attention, and new by-laws for houseboats in the river up to Teddington Lock, to secure them good drinking water, avoid nuisance, and prevent infectious disease, have come into force.

This is a valuable report, which should give the public confidence that it is being well protected against the importation of unsound food and infectious disease by the Port Sanitary Authority of London.

## CATCHING DISEASES EARLY.

"To educate the public in the care of its health" is the aim of the Middlesex Hospital Press Committee, and amongst other activities it has issued nine Health Leaflets for distribution. These have the following titles: Cancer of the womb; What should be known about cancer; The "change of life"; Infantile diarrhœa; Care of the teeth; The prevention of deafness; House flies and disease; Eye-strain; and Precautions to be observed by tuberculous patients. They have been written by members of the staff of the hospital, and medical officers of health and others are urged to use them as propaganda. So far over 36,000 have been sold to health authorities, and the committee allows these to print their own names at the head of the sheets if due acknowledgments to the hospital are made. The price shown on the sheets is 2*d*. each. As an example of the leaflets may be quoted that which deals with the prevention of deafness. It starts as follows:—

> "Severe deafness, unless due to wax, is rarely curable, but in many cases something can be done either to relieve it or prevent its increase. Slight deafness, especially if it has not lasted long, is much more often curable, hence in all cases expert medical advice should be sought directly impaired hearing is noticed. There are three principal causes of deafness: (1) wax or similar material blocking up the ear; (2) diseases of the mouth, nose, or throat; and (3) poisons which circulate in the blood and affect the nerve of hearing."

These statements are perfectly clear. When, however, the author later says "This [change in the drum] is especially likely to occur when the inflammation is chronic and due to nasal obstruction, mouth-*breathing, repeated sore-throats, or chronic nasal catarrh,*" we have some doubt whether he will carry all his readers intelligently along with him. The instruction of the leaflets is lucid and, on the whole, simple; but here and there expressions should be made even easier. Each leaflet might be submitted to a person of average intelligence for translation into the vernacular as far as this can be done without destroying its effect upon educated people. After a useful series of comments the writer on deafness continues:—

---

[1] THE LANCET, 1925, i., 1051.

[2] Navy Health Blue-book, 1922, p. 61.

[3] Arch. f. Schiffs- u. Tropen-Hygiene, October, 1925, p. 487.

> "The reader who has glanced through the above may regard it as a somewhat depressing story, but though little can be done to cure deafness, excepting in the earlier stages, there are various mechanical contrivances which magnify sounds and assist hearing, just as glasses give help in errors of sight. . . . The only way to cure or prevent deafness is to treat the causes that produce it, and *good can only be done in the early stages of the trouble.* Hence it is imperative not to delay, but at once to seek expert medical advice directly the slightest impairment of hearing is noticed."

The italics are ours, but they are reduced from the capital letters in the original. They may well form the war-cry of those who are trying to educate the public in health matters. Such publications as those of the Middlesex Hospital have as their object the awakening of personal alarm. In a neurotic generation this may seem superfluous; but counsel such as these pamphlets give may provide that extra stimulus which makes a nervous person face hearing the worst and at the same time it may save unimaginative people from disaster. And apart altogether from the attempt to arouse the right kind of self-consciousness in health matters—always a difficult task—there is much information in the leaflets that will be helpful to the people for whom it is intended.

## ROYAL SOCIETY OF MEDICINE.

SINCE their inception in 1919, the social evenings organised by this Society have been popular and well attended. The first of those arranged for the coming session will be held on Feb. 1st, at 8.30 P.M. Sir StClair Thomson, President of the Society, will receive the guests, and at 9.30 P.M. Dr. F. J. Poynton will give a short illustrated address on The Part Played by Doctors in the Early Days of Aeronautics. Later in the session Sir Humphry Rolleston will speak to a similar gathering on Some Worthies of the Cambridge Medical School, while the address planned for the evening of March 1st by Dr. Gustave Monod will be entitled From Cagliostro to Coué, or Imagination as a Method of Treatment. Dr. Monod is not the only distinguished foreigner whose visit is expected by the Society, since the Dermatological Section have invited Dr. C. Levaditi, of the Pasteur Institute, Paris, to address them on Recent Advances in the Chemotherapy of Syphilis. This lecture should prove attractive to members of most other sections of the Society, and may well form the occasion of a large and representative gathering.

## FASCIOLOPSIS INFECTION IN CHINA.

THE *American Journal of Hygiene* is performing a useful service to international hygiene by publishing a series of monographs, the most recent of which deals with fasciolopsiasis or infection with the intestinal fluke, *Fasciolopsis buski*, from the pen of Dr. Claude H. Barlow, of Shaohsing, China. It was in 1843 that Mr. George Busk, F.R.C.S., first discovered this very large trematode worm in the duodenum of a lascar who died in the Seamen's Hospital, and the parasite was named by Lankester in 1857, but it is only recently that the life-history and clinical effects of this fluke have been worked out. As now elucidated, the life cycle closely resembles that of the common liver fluke, *Fasciola hepatica*, and thus differs from the more typical trematode cycle in that the cercarial, or infective, stage escapes from its intermediate snail host and passes its encysted stage on certain pond plants, which constitute a local article of food. With these facts available, prevention of human infection would appear to be eminently simple, but it does not follow that such a conservative population as that of central China is likely to be greatly impressed by the promulgation of the scientific facts of the case or to derive immediate personal benefit therefrom. The theoretical simplicity of the prophylactic problem bears some analogy to that of hookworm, but the practical difficulty may be no less great. Fasciolopsiasis, however, appears to be a less serious affection than ankylostomiasis or schistosomiasis, its principal clinical features being intestinal disturbances and, in chronic cases, œdema. Interest in Dr. Barlow's report is heightened by an account of his personal symptoms following experimental auto-infection and his subsequent cure by means of the most up-to-date anthelmintic remedy, carbon tetrachloride.

## THE HEALTH VISITOR AND HER EDUCATION.

HEALTH visiting is, comparatively speaking, a new profession. It was in 1908 that the London County Council first empowered sanitary authorities in London to appoint women to be known as health visitors, whose duties were to include: (1) giving advice on the proper nurture and management of young children; (2) the promotion of cleanliness as the basis of health; (3) such other analogous duties as may be assigned to them. In the absence of any official pronouncement on the subject, it is hardly to be wondered at that widely divergent views have been held as to the most desirable training for the woman who is to fill this somewhat nebulous rôle, and even now no complete agreement has been arrived at. Some feel strongly that a three years' general nursing training should be insisted upon as the foundation in every case. This is in accordance with the American practice, where the public health nurse is, as a matter of course, a graduate of a hospital training school; and in this country the College of Nursing has recently arranged a course of training in preparation for the health visitor's certificate, for which none but the fully-trained nurse is eligible. On the other hand, there is a body of people, including medical men and women of such experience as Prof. H. R. Kenwood and Dr. Flora Shepherd, who have expressed the opinion that three years spent entirely in association with illness is actually detrimental to a health visitor, whose efforts, in so far as they are medical at all, deal with prevention and not with cure. Such essentials as a knowledge of anatomy, physiology, and asepsis can, they say, be acquired more quickly than by spending three years in hospital. Members of this school of thought insist on the social character of public health work, and consider that routine nursing in an institution does little to prepare the health visitor to help the mother in grappling with the problems of a working-class home.

While different views as to the best training have thus been held amongst those well qualified to judge, it has for a long time been recognised, especially by health visitors themselves, that a uniform standard should be accepted over the country as a whole, so that a certificate considered essential by one local authority should not be regarded as a disadvantage in another district. The regulations issued by the Ministry of Health, which came into force in April, 1925, represent a serious attempt to face the situation and to reduce to order the chaos of former permissible qualifications. The health visitor, under these regulations, gains a certificate after passing an examination conducted by the Royal Sanitary Institute—the central examining body appointed by the Ministry to hold examinations in various convenient centres—and she must either (*a*) be a trained nurse who has obtained the certificate of the Central Midwives Board, and has completed an approved course of training in public health work for at least six months; or (*b*) have undergone a course of training of two years' duration, already recognised under the Board of Education (Health Visitors' Training) Regulations, 1919, together with six months' training in hospital, and has obtained the certificate of the Central Midwives Board. In no case is a certificate now granted without the passing of this examination, which was held for the first time last October. Existing health visitors are safeguarded in that they may be reappointed without further qualification, and those with five years' service may sit for the examination without attending any special course of instruction; but from April 1st, 1928, no woman may be appointed for the first time as whole-time officer of a local authority with health visiting duties unless she has obtained the certificate. Those who have many years of service to their credit, as well as the best qualifications hitherto available, will evidently be at a disadvantage in applying for new appointments, as compared with the youngest health visitor who holds the Ministry's certificate, and it is doubtless to rectify this that the Ministry has recommended local authorities to give every opportunity to health visitors to obtain the certificate, and offers grants in aid to enable them to do so at a reasonable fee.

## "SHIP FEVERS."

FEVERS have always been the most prevalent and important of the diseases of seafaring men, but under this convenient term have been included illnesses of many different sorts. The advance of medicine in the last 30 years, particularly in the differentiation and recognition of diseases, has shown how many illnesses aboard ship are due to tropical disease, and especially to malaria. In a recent article[1] Prof. K. Sannemann illustrates this statement from his experience at the port of Hamburg. Twenty years ago Nocht estimated that malaria attacked 60 per cent. of the crews of ships trading to malarial regions. Prof. Sannemann himself found that, between 1908 and 1914, one-seventh of the medical cases coming to his notice on ships arriving at Hamburg were malarial, two-thirds of them from West Africa, one-eighth from the Caribbean Sea. Of the malarial cases 86 died and 2125 were received into hospital. Cases are not so frequent now as they were before the war, for quinine prophylaxis has become familiar both to owners and to sailors. Ships' doctors report improving results for, though prevention is not absolute, cases are fewer and slighter, and time lost through illness is reduced. That time-wasting tropical disease, dengue, is also met with on shipboard, and Prof. Sannemann finds that there are medical officers acquainted only with European diseases who do not treat amœbic dysentery with emetine and yatren. Doctors should, he thinks, not be put in charge of ships sailing to the tropics unless they have had a course in a school of tropical medicine. At present they have to report themselves to the port medical officer, who has only time to touch on the more important matters. Moreover, a doctor on board ship is sadly handicapped without a microscope.

## THE AMERICAN HEART JOURNAL.[2]

THE economic importance of rheumatic infection in childhood is being impressed on the Metropolitan Asylums Board by its medical officers, and we print substantially in full on p. 151 Dr. Gordon Pugh's report, in accepting which last Saturday the Board also accepted responsibility for the preventive treatment of cardiac complications. The care of heart disease when it has once occurred, especially as a factor of industrial importance, has received more general consideration in America than in this country, as a visit to one of the pioneer clinics in New York City, such as that of Dr. Wyckoff, at the Belle Vue Hospital, or that of Dr. St. Laurence, at St. Luke's Hospital, will show. Of these the former is an evening clinic, dealing solely with adults whose disability is not yet sufficient to prevent them carrying on their employment. The cost to the hospital is small, for not only do the medical officers give their services in a purely honorary capacity, but almost the entire clerical and administrative staff consists of voluntary workers, who, after a hard day's work in the city, devote their evening to the work of the clinic. Their labour is rewarded, for there are few departments of medicine in which results are so soon to be seen; the patients fully realise that, but for the advice and treatment which they receive week by week at the clinic, many of them would no longer be able to support themselves and their families. At the children's clinic at St. Luke's Hospital the picture is no less pleasing. Here many cases of incipient heart disease are arrested in the early stages, so that children, who would otherwise have been crippled for life, grow up to be useful members of society. The clinic also includes a group of "potential cardiac cases"—namely, children who have suffered from rheumatic fever or chorea, but have not hitherto manifested any signs of heart disease. Careful supervision may prevent some of these from developing cardiac lesions. In the diagnosis of heart disease considerable progress has been made during the past quarter of a century, as the result of the advance in our knowledge of the cardiac mechanism; but in its treatment, apart from the more rational use of drugs, there is little to show. To speak of "cure" in connexion with organic heart disease is hardly permissible, but concerning its prevention and relief there is still much to learn; and in these two branches of therapeutics the statistics compiled by the American Heart Association will have permanent value.

This Association has undertaken the task of organising the study of heart disease on a large scale, and the first number of its official organ, the *American Heart Journal*, appeared in October last, with the primary object of rendering more easily accessible papers on various aspects of heart disease, previously scattered in less specialised journals. Although primarily clinical in character, and designed to appeal to the general practitioner as well as to the heart specialist, this journal will contain original articles dealing with the more purely scientific and public health aspects of the subject, critical reviews, and abstracts of important articles in the current literature. The first number opens with an article by Dr. Aldred Scott Warthin, giving the clinical histories and pathological findings in eight cases of sudden death due to exacerbation of latent syphilitic myocarditis. The extremely abrupt onset of severe symptoms, in apparently healthy men, was a very striking feature, for in only one of these cases did the fatal illness last for more than a few days. The myocardial lesions were found to be crowded with spirochætes, and the cell infiltrations were predominantly polymorphonuclear, resembling those of the rapidly developing lesions seen in experimental animal syphilis, as opposed to the round-celled infiltration of the more chronic process. Another original communication dealing with a rare and interesting condition is that by Drs. Samuel Bradbury and Cary Eggleston on Postural Hypotension. Three cases are described in which assumption of the erect posture was associated with a remarkable and persistent fall in both systolic and diastolic pressures. All these patients were liable to syncopal attacks, exhibited a total inability to perspire, and had a slow pulse-rate. The reaction of the patients to certain drugs led the writers to suggest that the condition is probably due to paralysis of the sympathetic vaso-constrictor nerve-endings. Dr. E. Libman discusses the prognosis in a series of 800 cases of subacute bacterial endocarditis. Drs. Frederick A. Willius and Samuel F. Haines give an analysis of the cardiac findings in 162 cases of myxœdema. Drs. Samuel A. Levine and Francis C. Newton, in a paper dealing with the operative treatment of angina pectoris, give the clinical and laboratory findings in eight cases in which sympathectomy was performed, and discuss the selection of cases suitable for this operation. Drs. Paul D. White and Merrill M. Myers give a comprehensive classification of cardiac diagnosis. Drs. James G. Carr and John D. McLean have articles dealing with the public health aspect of heart disease. Drs. William J. Kerr and Stacy R. Mettier review the literature dealing with the blood-supply of the heart valves. They describe their own observations on the pig, and discuss the embolic theory of endocarditis in the light of these findings. Drs. George R. Herrmann and Frank N. Wilson describe a new electrode with a very low external resistance, suitable both for clinical and for experimental electrocardiography. We feel sure this new journal will serve a useful purpose in bringing recent advances in cardiology before the notice of a wider public, and especially in directing attention to the all-important subject of prevention.

## THE LABORATORY DIAGNOSIS OF SMALL-POX.

WITH the increasing occurrence in several northern and midland counties of the mild form of small-pox it is obvious that any serological or similar method of identifying this disease would be of the greatest service. During the years 1924 and 1925 there were a certain number of cases of suspected small-pox in Belgium, and Dr. L. van Boeckel carried out an important series of investigations on 12 cases where the diagnosis was doubtful. The results of this have been recently published,[1] and if the experimental work can be confirmed an important addition to the methods of diagnosing small-pox will be available. Clinically, all 12 cases ran the course of mild small-pox, or, as Dr. Boeckel prefers to call it, alastrim, following the modern accepted views on the symptoms and signs of this disease. The experimental work consisted of attempting to vaccinate the patients, examination of their blood, Paul's reaction, examination for the corpuscles of Guarnieri, and complement-fixation tests. Vaccination and blood counts were carried out in the ordinary way. Paul's reaction consists in removing some of the liquid contents of a vesicle, or using a suspension of dried and powdered crusts, which is suitably diluted and placed on the scarified surface of a rabbit's cornea, the other eye being used as a control. At the end of 40 to 48 hours small elevations appear on the surface of the inoculated eye if the reaction is positive, as it is held to be constantly if material from a case of small-pox or vaccinia be used. In alastrim the reaction is inconstant and feeble, while it is always negative in chicken-pox. On microscopical examination of the rabbit's cornea thus treated certain round or oval collections of bodies are to be found, known as the corpuscles of Guarnieri. These are said to be pathognomonic of small-pox, although somewhat divergent results indicate that they may be present if alastrim vesicle lymph has been used. The complement-deviation experiments appear to be of great interest. Both the vesicles and pustules of the small-pox eruption contain a specific antigen and the serum of a small-pox patient contains specific antibodies. These bodies are similar to those for vaccinia, but quite distinct from those of chicken-pox. The specific antibodies appear in the blood during the stage of vesiculation and disappear during desquamation. In the case of chicken-pox specific antigens and antibodies are also found. The difficulties with regard to obtaining fresh small-pox lymph to act as antigen in carrying out complement-fixation experiments have been got over by using dried vaccine lymph which has been found to answer the purpose well and can be stored and emulsified before use. In the case of chicken-pox the antigen used consists of dried and powdered crusts which are emulsified in saline before use. After various experiments the necessary amounts of complement, antigen, and serum have been worked out and the method applied with suitable controls to the 12 cases already mentioned. Dr. Boeckel emphasises that no one laboratory test should be relied upon for the diagnosis of small-pox, but that all five enumerated above should be employed in each case. He claims that if this be done it is almost always possible to differentiate between chicken-pox and small-pox in a doubtful case. Thus, in one case of a miner, aged 25, who had been successfully vaccinated and revaccinated, a specific fever occurred which corresponded to the classical descriptions of alastrim. Vaccination on the eighth day of the disease was negative, there was a leucopenia with a relative leucocytosis (as occurs in chicken-pox), the Paul reaction was negative, and no corpuscles of Guarnieri were found. The complement-fixation test was negative with small-pox antigen and positive with chicken-pox antigen. The diagnosis of chicken-pox was therefore made with some certainty. It is unfortunate that these researches have not enabled Dr. Boeckel to differentiate alastrim in any satisfactory manner as a specific disease. He points out as an added difficulty from the clinical point of view that chicken-pox appears to take the form of alastrim quite as often as does small-pox: this is, we believe, not the experience of clinical observers in this country.

## THE OTAGO MEDICAL SCHOOL.

JUDGING from a volume[1] which has lately reached us, the methods of instruction at the Medical School of the University of Otago, Dunedin, N.Z., are progressive and must be stimulating. It consists of 13 papers reprinted from the *New Zealand Medical Journal*, the *Journal of Pathology and Bacteriology*, and THE LANCET, and is wholly the work of hospital residents, assistants and demonstrators, and senior medical students. A systematic attempt is made to encourage independent work, and though, of course, a great deal that is produced is not more permanent than academic exercises should be, the present issue of the Proceedings shows that a certain amount is done which is obviously useful to others as well as to the authors. There are papers on some anatomical anomalies, the serum treatment of pneumonia, the treatment of fractures of the forearm, virulent staphylococcal infections, complement fixation in the diagnosis of gonorrhœa, and other interesting subjects. So much of medicine, surgery, and pathology is the same all the world over that the topics are of general interest everywhere. The only article of nominally local character deals with diabetes in New Zealand, and shows that its prevalence is rather greater than in England and rather less than in the United States, and has increased in recent years as it has elsewhere. The plan of stimulating senior students and young undergraduates to plunge into original inquiries at the earliest possible time is not without its dangers. It may and does lead to the publication of many papers which are records of time spent rather than contributions to the advancement of knowledge, and sufficient care is not always taken that the inquirers are adequately grounded in a wide elementary knowledge of their subject. But as a piece of academic training, imposed on an adequate preliminary preparation, it is unrivalled, and with due restraint in publication should be more widely adopted than is done at present.

WE regret to announce the death, at the early age of 41, of Dr. George Herbert Hunt, physician to Guy's Hospital.

THE sudden death took place at Bradford on Jan. 12th of Mr. Basil Hall, honorary consulting surgeon to the Bradford Royal Infirmary and lately President of the British Medical Association.

## INDEX TO "THE LANCET," VOL. II., 1925.

THE Index and Title-page to Vol. II., 1925, which was completed with the issue of Dec. 26th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLVI.

## THE TREATMENT OF TINNITUS AURIUM.

The treatment of tinnitus is unfortunately often disappointing, and it must be admitted that advance in this direction is in no way commensurate with that along other paths of knowledge of aural disease. The fundamental difficulty lies in lack of knowledge of the pathology of tinnitus, with the result that treatment must be largely empirical and based on clinical observation of the use of various drugs. Since tinnitus is an accompaniment of most forms of ear disease the subject is a large one; indeed, the author of one large text-book states that "treatment of subjective noises is as broad as the subject of ear and brain diseases." This statement is no doubt true; nevertheless it is perhaps helpful to condense what is known in the treatment of a symptom which is always annoying and frequently distressing.

Though many cases must be treated empirically there remains a number that may be relieved by treating an objective cause. Investigation of a case of tinnitus must be systematic and thorough in order to eliminate this possible cause before falling back on well-tried drugs.

Cases may in the first place be divided into two groups: (*a*) Those without deafness, very small compared with (*b*) those in which tinnitus accompanies deafness. In passing it must be noted that patients' statements as to deafness are unreliable, and after examination many who at first sight are regarded as group (*a*) pass to swell group (*b*).

### *Cases of Tinnitus without Deafness.*

The question of general health must be gone into and treated; constipation, renal conditions, vascular system, including heart and blood pressure, anæmia, functional nervous disease, neurasthenia, exhaustion, physical and mental, also excess of tobacco and alcohol. Certain "referred" causes must receive attention. Investigation must include the *teeth*; unerupted molars may cause tinnitus, and an X ray examination of the jaws and subsequent extraction may cure the noises. Even carious teeth may be a cause of tinnitus. The *accessory nasal sinuses* must come under suspicion and must be investigated for the presence of suppuration. The *nasopharynx*, too, may show some abnormality, though, as a rule, in cases of nasopharyngeal disease (adenoids, growth), deafness usually accompanies tinnitus. The *tonsils* must not be overlooked, since undoubtedly some unexplained cases of tinnitus are due to toxic absorption from tonsils and removal has been followed by cessation of tinnitus. In this group are placed those cases in which the tinnitus is not a true tinnitus but an hallucination; the patient hears voices and sentences, a condition almost always indicating serious mental disease.

### *Tinnitus with Deafness.*

Though there is no real evidence as to the cause of tinnitus it appears to be true that any pressure on the foot-piece of the stapes makes for tinnitus (this can be shown by the fact that pressure on the normal membrane with a probe produces tinnitus), so that relief of any existing pressure should relieve the patient. The cases in this group may be subdivided into (1) cases with objective signs of disease, and (2) those without objective signs.

### *Cases with Objective Signs.*

In these patients examination must be made of (*a*) the external auditory meatus, (*b*) the tympanic membrane, (*c*) the Eustachian tube.

(*a*) The *external auditory meatus* must be examined for wax, foreign bodies, polypi, osteomata; treatment of these conditions if found is obvious.

(*b*) The *tympanic membrane* must be examined for signs of middle-ear affections. The membrane may show signs of acute inflammation, redness or bulging, or recent perforation; in these conditions the tinnitus is usually described as pulsating or blowing; subsidence of the acute condition usually leads to cessation of the tinnitus. There may be an exudative middle-ear catarrh, as shown by slight changes in the colour of the membrane and by a hair-like line on the membrane. This line is concave upwards and is made by the surface of the fluid in the tympanum and moves with movement of the head. With this condition the tinnitus complained of is of water moving or, in more chronic cases, of creaking, or of "two pieces of leather being rubbed on one another."

*Treatment* consists in inflation of the Eustachian tube and instillation of drops of glyc.-acid-carbol.; if unsuccessful the membrane is incised under strict asepsis or antisepsis and the fluid sucked out with Siegle's speculum or blown out by means of the Eustachian catheter; removal of the fluid immediately removes the noise.

The membrane may show old-standing perforations or scars of perforations or atrophic patches, but treatment of these conditions locally is usually useless as far as tinnitus goes, since they indicate chronic infections and adhesions.

It has been long recognised that the rarefaction of the air in the external auditory meatus often diminishes the noise, and when such is the case vibratory massage of the drum is well worth carrying out and should be practised for about five minutes on three or four occasions. Retraction of the membrane is very often associated with tinnitus in its severest form.

(*c*) The *Eustachian tube* is vitally important; any catarrhal condition of the upper respiratory tract may cause catarrh of the Eustachian tube; this condition results in retraction of the membrane, and it is impossible to dissociate conditions of the membrane and abnormalities of the tube.

*Treatment.*—Inflation of the tube by means of the catheter in recent cases may lead to immediate cessation of the noises; this proceeding may want repeating on three or four occasions. Inflation of air alone is not always successful, but good results may be obtained by inflation of warm air, vapour of chloroform, or ether; or again by inflation of a few drops of a 5 per cent. solution of methyl salicylate in parolein through the catheter. In obstruction of the tube the passage of a Eustachian bougie gives excellent results. In recent cases these local measures meet with a considerable degree of success; but when the middle-ear catarrh is chronic local measures often fail and from a treatment point of view the cases must be placed in the next class to be considered.

### *Cases without Objective Signs.*

Tinnitus with deafness includes a large number of cases in which there is no objective lesion amenable to local treatment, in which the Eustachian tube is clear, the membrane normal and no sign of pharyngeal or nasopharyngeal infection; broadly speaking, the cases are those of internal ear deafness and otosclerosis. The term internal ear deafness is given to a very large group of cases with very varying pathologies. From the point of view of treatment cases of chronic middle-ear catarrh must be included.

*Treatment.*—Whatever the cause of the deafness, and it is often quite unknown, treatment of the tinnitus runs on similar lines; drugs and general advice with encouragement. The best drug is no doubt dilute hydro-bromic acid, and it should be given in full doses of ʒi., three times a day in water; it may be combined with small doses of potass. iodid.; small doses of quinine (gr. i., t.d.s.) help other cases. The condition of the blood pressure is of some help; in cases of high blood pressure doses of trinitrin often give good results. On the other hand, with low blood pressure ernutin should be given and digitalis may well be combined with acid. hydrobrom. dil. Thyroid extract gives encouraging results, especially in cases about the menopause. Pilocarpine nitrate, gr. 1/12, twice a day in a mixture, is sometimes of value. Luminal, gr. ½, three times a day, may be given and the doses carefully increased if need be.

The general advice deals with the patient's health and habits. He should avoid excess of alcohol and tobacco; indeed, tobacco should be stopped. Some people improve with change of environment, in others life at a high altitude causes cessation of the noises. Regular exercise and treatment of constipation should be insisted on. Many patients have a dread, often kept secret, that the noises are going to affect the brain, and reassurance helps them to support what is a depressing burden, especially when the noises are so severe as to prevent sleep. It has been suggested, and carried out with success, that patients should keep a very loud-ticking clock near their beds, so that their attention may thus be distracted from their head noises. Hypnotics should be given to these severe cases. It is these very obstinate cases, so distressing that the victims threaten suicide, which have led to the suggestion of operation on the cochlea or eighth nerve. Unfortunately the few operations that have been carried out have not justified themselves, since the tinnitus has continued in patients who survived the operation.

W. M. MOLLISON, M.Ch. Camb., F.R.C.S. Eng.
Surgeon, Ear and Throat Department, Guy's Hospital.

## RHEUMATIC INFECTION IN CHILDHOOD:

### FACILITIES FOR PROLONGED TREATMENT.

A REPORT on rheumatism in childhood was submitted to the Metropolitan Asylums Board on Jan. 9th by Dr. W. T. Gordon Pugh, chief medical officer of the Board's children's and surgical tuberculosis services. Dr. Pugh reproduces in his report the considered opinions of various authorities and has collected information on the facilities available for treatment in the London area. The subject is of such interest and importance that we reproduce the substance of Dr. Pugh's report.

### *Extent of the Evil.*

In 1923, says Dr. Pugh, one-eighth of the deaths in England and Wales were registered as being due to heart disease, and it has been estimated that one-half of all cases of heart disease are of the rheumatic type. In a prolonged investigation at Bristol Dr. Carey Coombs found that in two-thirds of his cases the disease commenced between the ages of 5 and 15, and if these data are correct it follows that rheumatism in childhood is eventually responsible for one twenty-fourth of all deaths. In the past insufficient attention has undoubtedly been paid by health authorities to the prevention and treatment of rheumatic fever in children. Cardiac cripples have not received from them the sympathy and care that tuberculous and paralysed cripples have received, possibly because they are less conspicuously in evidence. There are signs, however, that public interest is awakening.

### *Manifestations of Rheumatism in Children.*

Rheumatic fever, as Dr. Pugh remarks, is exceedingly rare in infancy and uncommon under the age of 5. After 5 it is, of course, not only one of the most frequent diseases of childhood but one of the most serious, differing from the same disease in adults in that joint affection is a much less prominent symptom, which may, indeed, be altogether absent. Taking its commoner forms, there are two principal groups: those beginning with sore-throat, arthritis, and carditis, and those beginning with chorea, often associated with carditis, but sometimes not. In 1108 cases observed by Dr F. J. Poynton[1] carditis occurred in 60 per cent., arthritis in 56 per cent., chorea in 55 per cent., and sore-throat in 30 per cent.

### *Incidence in London School-children.*

The school medical officer of the London County Council reports that a census of children absent for over three months is taken once a year, and that in November, 1924, it was found that there were 2088 children who had been absent for this period, of whom 972 were absent on account of rheumatism of the heart and chorea During 1924 there were admitted to the physically defective schools 271 children with acquired heart disease. Among about 10,000 children examined at ordinary routine inspections by Dr. Nairn Dobbie (i e , excluding the worst cases who either do not attend school or are early admitted to a physically defective school), definite evidence of acquired carditis was found in 0·1 per cent. of children under 5 years, in 0·25 per cent. at 7 years, and in 0·7 per cent. at 12 years. In 90 per cent of all these cases of structural alteration of the heart there was a history of rheumatic fever, definite chorea, recurrent pains and repeated tonsillitis, either singly or combined In the remaining 10 per cent. the only illnesses recorded were scarlet fever, diphtheria, influenza, measles, or whooping-cough.

### *Indications in Management.*

Much depends, continues Dr. Pugh, upon the treatment which the child receives in his first attack. From the administrative aspect there are two indications in treatment :—

(1) *The healing of the heart condition,* so far as it can be healed, by rest and regulated exercise.—The horizontal position reduces blood pressure and cardiac action, and lessens the danger of cardiac complications; rest in bed at least until the pulse-rate is normal is essential. How nearly this rest should be absolute and how long it should be continued are matters for investigation. Dr. R. Miller advocates prolonged quiet rather than strict rest; and Dr. Poynton says that convalescence from rheumatic carditis should be a history of graded exertion and not aimless rest. Others, with facilities for providing a more prolonged recumbency than voluntary hospitals can afford, favour an extension of the period of complete rest. On the general subject of management a letter from Sir Archibald Garrod may be quoted:

> "In some cases of children of medical men, for whom one can ensure the necessary care and rest, I have seen results which have enabled me to realise how much might be accomplished could the necessary conditions be ensured. I can express my confident belief that an organisation which rendered it possible to give two or three months' rest in bed to all children with rheumatic fever would reduce very materially the severity and frequency of what is commonly spoken of as 'heart disease' amongst the adults of the community"

(2) *The building up of the resistance of the tissues to help them to overcome the tendency to further attacks.*—This is more debatable, for the cause of relapses is not definitely understood. Dr. Miller says :—

> "Whence come these later attacks? Are they from the alimentary tract, the mouth, or the bowel, or do they originate from foci left encapsulated in the tissues of the body? In some cases it would seem that they are not really fresh attacks, but recrudescences of an infection which has never truly been quiescent. I confess that this whole subject, important though it is, is full of mystery to me."

Whether the prevention of relapses depends on freeing the patient from the infection or on building up his resistance, treatment for a considerable period in hygienic country surroundings seems to be indicated. Dr. Poynton, advising prolonged care in the country for sufferers from rheumatic heart disease after the acute phase is over, says:

---

[1] Brit. Med Jour., 1923, i., 919.

> "Will these measures prevent relapses in the future? The answer seems to me plain; until we have a specific remedy the most we can expect is that by giving children time to consolidate the recovery of their hearts, and by assisting nature to build up the resistance of their body tissues, we certainly help them to repel future attacks. After puberty the tendency to cardiac rheumatism diminishes, and thus we have the right to believe, until it is proved to the contrary, that a number of these cases will escape further attacks. Fresh air, rest, and education will not themselves arrest rheumatism, but they are sure steps in its prevention."

### *Existing Accommodation in London.*

(1) *Children's Hospitals.*—There are six London children's hospitals, and Dr. Pugh has summarised the statistics for 1924 of the five which publish annual medical reports. The total accommodation was 706 beds; these received 10,096 in-patients, of whom 377 (or 3·7 per cent.) suffered from rheumatism or its effects (rheumatism, 99; morbus cordis, 117; chorea 161). The pressure on the accommodation of voluntary hospitals calls for a somewhat rapid passage of patients and the average stay, omitting cases of adenoids, varied from 20 to 30 days. The stay of rheumatic cases is generally longer; at the Hospital for Sick Children, Great Ormond-street, it averaged 60 days in 1919–20. Some children's hospitals have their own convalescent homes and are able to transfer a small number of their rheumatic cases to them; a few cases are transferred to special country homes of limited accommodation; sometimes it is necessary to send these patients home to await vacancies. Physicians have long lamented the necessity for the premature return of rheumatic cases to their homes, and Dr. Miller, remarking that pressure on hospital beds made prolonged treatment impossible, continues:

> "The ordinary convalescent home in the country or at the seaside is too lively a place for the chronic heart case. I think most physicians have quite given up sending such cases to convalescent homes even where they will be accepted.

(2) *General Hospitals.*—Many cases are treated at general hospitals, but as children are not separated from adults in the statistics, it is not possible to ascertain the number. The difficulty of providing treatment of sufficient length is even greater than in children's hospitals. A letter from the almoner of Guy's Hospital may be quoted:

> "I think it may interest you to know that 52 children have to my knowledge been sent to infirmaries during the past three months from the out-patients' department here, suffering from rheumatism or chorea in an acute stage; and 16 have been referred to the Invalid Children's Aid Association for institutional treatment. Even these figures do not represent the total number of acute cases, and the number of children with subacute rheumatism attending as out-patients at intervals would be difficult to ascertain. It must, however, be very large and, on the principle that prevention is better than cure, it would appear that these early cases should be given as much consideration as the acute cases. The children who are seriously ill are usually referred to me by the physicians with a request to provide immediate nursing treatment under skilled medical supervision, followed by prolonged convalescent treatment under supervision to ensure the best results. Few of these children can be admitted to such a hospital as this owing to the pressure on beds here, which precludes the possibility of blocking many with these very prolonged cases. Immediate admission to the infirmary for treatment during the acute stage, with a view to transfer when fit to a M.A.B. hospital, such as Queen Mary's or The Downs, has seemed to us to be the best solution of the problem at present; but, unfortunately, experience shows that the children do not always go to a M.A.B. institution, and we have record of cases in which children have returned to this hospital, for perhaps the third time within a few months, with symptoms of acute rheumatism, having been nursed for short periods in the infirmary and then discharged to their homes. The few that are admitted to the wards here also present a problem as, being the more severe cases, transfer to a suitable institution is especially desirable as soon as the acute symptoms have subsided. Unfortunately the voluntary societies have neither the accommodation nor the funds for many such long and difficult cases."

(3) *Guardians' Hospitals.*—These take a much greater part in the treatment of acute cases than is generally appreciated. Statistics are not published, but in Southwark Hospital in 1924 55 cases of acute rheumatism and chorea in childhood were treated, and 72 days was the average length of their stay. All of them were admitted direct from their homes. Thirty-four of these patients were transferred from Southwark to M.A.B. country hospitals for further treatment. The total number of rheumatic children received at the Board's country hospitals from the guardians' hospitals and discharged in 1924 was 228 (carditis, 120; chorea, 90; debility after rheumatism, 18); the average stay in the country hospital was 136 days for cases of carditis and 90 days for cases of chorea. Children treated at the guardians' hospitals thus have the advantage that their stay can be longer and they have the opportunity of transfer to one of the Board's country hospitals or seaside homes.

### *Treatment at M.A.B. Hospitals.*

A memorandum from the Invalid Children's Aid Association submitted to the London County Council in November points out two practical difficulties in obtaining treatment in the Board's country hospitals—viz., the natural objection of self-supporting parents to application to the Poor-law and the almost insuperable difficulties in the path of a direct transfer from the wards of a voluntary hospital to these institutions. It suggests that the Council should take beds in voluntary homes for heart cases, and recommends that direct admission to the Board's hospitals should be arranged to avoid the intermediate agency of the Boards of Guardians. On the latter subject Dr. Pugh has interviewed officials of the Ministry of Health, and gathers that since acute rheumatism may be regarded as a "fever," it is unlikely that any objection will be raised to such patients being admitted to the Board's hospitals in the same way as other fever cases.

*The Ideal Facilities.*—Last year, we may recall, in a report on rheumatic diseases among insured persons, Sir George Newman said:

> "The concentration of acute rheumatic cases in a special hospital with cardiological and pathological departments, preferably situated in a country district, would probably be followed by a great advance in our knowledge of the disease and of the prevention of valvular disease of the heart."

He remarked that medical opinion had advised what almost amounted to bed sanatorium treatment for convalescent patients in special homes of recovery. In a report to the Board of Education in September, 1925, he says:

> "There can be no doubt that children suffering from rheumatic infection are better for early hospital treatment, and there is need for more institutional accommodation for such children. Preferably they should not be mixed with other invalid children, but dealt with in separate open-air hospitals or residential recovery schools, where 'team' and co-operative research can be undertaken into differential diagnosis and causation, and where suitable treatment, training of the body, education of the mind, and prolonged convalescence are available. The admission to such institutions should be upon a selection basis, and much care, skill, and foresight are necessary to their proper management. Something much more than the ordinary convalescent home is necessary, and obviously the means of treatment will vary for cardiac, choreic, or arthritic cases."

### *Dr. Gordon Pugh's Report Adopted.*

Having considered Dr. Gordon Pugh's report, the Metropolitan Asylums Board adopted his suggestion that accommodation for rheumatic children should be provided at Queen Mary's Hospital for Children, Carshalton, Surrey. Application for sanction to this proposal will be made to the Ministry of Health.

---

Dr. George Mitchell Winter, of Torquay, who recently resigned his seat on the Torquay Town Council after having been a member for a quarter of a century and deputy-mayor for several years, is to be presented with the freedom of the borough.

# MEDICINE AND THE LAW.

### *Cancer in Tar-Workers.*

A RECENT inquest in Manchester indicated once more the danger of cancer where workmen are employed in contact with tarry substances. The deceased man had worked for 24 years at the Bradford-road gas-works of the Manchester Corporation. According to the evidence reported in the *Manchester Evening Chronicle*, he developed a growth on the knee in 1918, underwent operation at Manchester Royal Infirmary, and resumed work at the end of that year. Another growth formed in 1923, and after a second operation he again took up his work, but finally gave it up at the end of 1924. The coroner, Mr. C. W. W. Surridge, said there was no doubt that death was occasioned by the cancerous growth due to the nature of his work, and a verdict to that effect was returned. The manager of the gas-works, who stated that this was the first case of the kind to come to his notice, though a second case has since been reported, was questioned by the coroner as to the possible use of protective clothing. He replied that there had been difficulty in finding suitable clothing and that rubber had not been found satisfactory. Dr. W. Faith, who also gave evidence, advised that workmen thus employed should be periodically examined in order that early operation might be performed where a growth was discovered. The coroner recommended that some such system of examination should be adopted.

It will be recalled that in November, 1919, a Special Order of the Home Office, made under Section 73 of the Factory and Workshop Act, applied that section (notification of disease) to epitheliomatous ulceration due to tar, pitch, bitumen, mineral oil, or paraffin, or any compound or residue of these substances, occurring in a factory or workshop. Regulations enjoining the use of protective clothing, gloves, &c., in trades specially classed as dangerous have not infrequently been made under Section 79 of the Act. In particular, the Chemical Works Regulations of 1922 contain provisions of this nature, but they are expressly excluded from application to the "manufacture and necessary purification of coal gas, water gas and producer gas for lighting, heating, and power purposes." Pending fresh legislation the special need appears to be, as the coroner observed, that workers should voluntarily submit themselves for examination at the first suspicion of any trouble. It should not be impossible to bring to the knowledge of all workmen concerned the protection which early treatment provides and the danger of delay.

### *Guardianship of Infants Act: a Magistrate's Protest.*

The Guardianship of Infants Act of 1925 may not be a matter of direct professional concern to medical practitioners. But it seems to be serving a useful purpose in reminding persons who are interested in social reforms of the fact that most new measures of social reform throw fresh duties upon either the county court judge or the justice of the peace, and that, in the interests of successful administration, Parliament had better indicate the lines on which those duties are to be discharged. Until last year the Chancery Division, acting as the deputy of H.M. the King, who is the father of his country, had a virtual monopoly of the jurisdiction over the guardianship of infants. The Act of 1925 entrusted a large part of this jurisdiction to magistrates. Thus it happened that Mr. Bingley, the stipendiary sitting at Marylebone police-court, has recently had to adjudicate upon a summons taken out by a husband against his wife for the return to him of their child, aged 4. Now the Act possesses the somewhat unusual feature of a preamble, and the preamble recites the modern acceptance of the principle of sex equality. The Act proceeds to declare that the Courts in deciding upon the custody or upbringing of an infant or the administration of its property shall regard the welfare of the infant as the first and paramount consideration, and shall not take into consideration whether from any other point of view the claim of the father or any right possessed by him at common law is superior to that of the mother, or the claim of the mother is superior to that of the father. The Act also gives the mother equal rights with the father of making applications to the Court. Mr. Bingley is reported by the *Times* to have observed that those who drafted the Act did not seem to have understood the basis of our laws. Apparently, he said, the framers of the Act assumed that a father had powers under the Act, but they did not give him any. It was an instance of the fresh difficulties which the legislature had put upon magistrates in calling upon them to decide matters formerly dealt with by the Chancery Division of the High Court. The Act was extremely vague and did not say that fathers had any right to their children. It was amazing that magistrates should be called upon to construe this Act in these circumstances. He assumed that, as the mother was stated to have equal rights with the father, the father also had certain rights, but the onus put upon magistrates by the Act was terrible.

It may be hoped that other magistrates will not be so easily appalled. The present position is not really so incomprehensible. The common law always favoured the father. The father of a legitimate child was something more than its guardian, for he could determine its religion, which a guardian could not. He had a right to the custody of the child and to the control of its education. Even if he made an agreement before or after marriage by which he purported to surrender this right, the Courts would hold such agreements to be void as against public policy, though in 1873 the mother's right to custody of a child under a separation deed was recognised. In 1839 the Court of Chancery was given power to take a child away from the father and give it to the custody of the mother until it was 7 years of age. In 1873 the age-limit was raised to 16. In administering these provisions the Chancery Court had special regard to the interests of the child and to the conduct of the father. In 1895 courts of summary jurisdiction were authorised to give a married woman the legal custody of her children under 16 as against the father, and, of course, orders as to the custody of the children have long been a well-known feature of matrimonial causes. Thus, in spite of its acknowledgment of sex equality, the new Act is not so very revolutionary after all. Indeed, the principle that the interests of the children shall be the paramount consideration with the Court has been an express doctrine in Chancery for nearly 50 years. No doubt it is true that the common law rights of the father still counted for something. For instance, the Chancery Courts would hold that a father living in constant debauchery and open adultery was unfit to have the control of his children; on the other hand, occasional incontinence or even living in adultery, provided that the children were not brought in contact with the adulterers, was held no ground for interference with him. It was this inequality of the sexes, this surviving modicum of the father's common law rights, which the 1925 Act set itself—a little rhetorically—to remove. Henceforward the magistrate is not to favour either father or mother as such, but merely to consider whether the one will do the child more good than the other. As for the common law rights of the father, whatever they may have been, the Act says they may now be disregarded. As for the legal learning of the Court of Chancery, it is not book knowledge that our magistrates will require in administering the delicate and difficult duties now imposed upon them.

---

NORTHERN INFIRMARY, INVERNESS.—The Mackintosh of Mackintosh has issued an appeal for £100,000 for the reconstruction, extension, and endowment of the Northern Infirmary, Inverness, which is the general hospital for an area comprising the counties of Inverness, Nairn and Moray, Caithness, Sutherland, and Ross and Cromarty. The infirmary was built a century and a quarter ago and is now, in spite of additions and improvements, inadequate and entirely out of date.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *Dichloren as an Anæsthetic.*

Prof. Paul Albrecht discussed recently before the Vienna College of Practitioners the advantages of *dichloren* (dichlorethylene) as a general anæsthetic. He has tried it in more than 500 cases during the last two years. He employs two mixtures; the first contains 1 part dichloren to 2 parts pure ether, and the second, 1 part dichloren to 3 parts ether. Administration is preceded by a hypodermic injection of 0·02 g. (nearly ⅓ gr.) of morphia and 1 mg. (1/70 gr.) of atropine half an hour before operation. Similar preparation, with appropriately smaller doses, is required in children. The new anæsthetic produces no fall in blood pressure and no damage to the tissues. In half the cases there is no excitement, and the patients are easily brought under anæsthesia. Sometimes twitching is noticed, but the only unpleasant complication observed has been spasm of the glottis or diaphragm, which occurred in 5 per cent. of the cases. Albrecht advises the open (drop) method, starting with a few drops and then increasing the rate of flow. At the end of 5–10 minutes there is always relaxation of the muscles sufficient for the most extensive abdominal operation. The use of dichloren markedly diminishes the amount of ether required, so that no more than about 30 g. of dichloren and 90 g. of ether are used per hour. Eighty-eight per cent. of all his operations with the new method were absolutely free from any inconvenience. In 5 per cent. the spasms mentioned above occurred—they were removed by increasing the rate of flow of the anæsthetic—and in another 5 per cent. there was cyanosis, or excitement, or lack of relaxation. These troubles were mainly seen in alcoholics, neurasthenics, or excessive smokers. He found that lobelia gives excellent results in cyanosis; a hypodermic of 0·02 g. (⅓ gr.) restores breathing rapidly. In one case, a woman of 72 years, operated on for incarcerated umbilical hernia, death occurred during dichloren anæsthesia; a severe extensive fatty degeneration of the myocardium was found at the post-mortem. Awakening after anæsthesia is rapid and free from any inconvenience in over 70 per cent. of cases. Pulmonary complications after dichloren are seen in 8 per cent. of cases, compared with 10 per cent. after the old ether-chloroform method. Whilst chloroform damages the vasomotor system, the myocardium, and the parenchymatous organs—not to mention its delayed results—dichloren does not produce any of these effects.

### *Death of Two Scientists.*

The medical faculty of the University of Vienna has sustained a severe loss by the death of Prof. Julius Bartel and Prof. Hans Pollitzer, two of its youngest but most active members. Bartel's name is well known to students of pathological anatomy and especially to those working on tuberculosis and constitutional disorders. He reached only the age of 52 years, but during the last 25 years was the actual, though not the nominal, head of the post-mortem room of the Vienna General Hospital. Whilst still a young student he published a series of papers on the morphology of tumours and on endocarditis, and later, at the suggestion of Weichselbaum, investigated the mode and portals of bacterial infection, especially by tuberculosis, and represented Austria at the Sixth International Congress on Tuberculosis in Washington. Prof. Bartel paid great attention to the lymphatic system and to the problem of constitution. He combined clear observation with speculation, and thus turned to the influence of climatic factors on health and mortality, publishing an outline of a work on this subject which his sudden death has not allowed him to complete. Prof. Pollitzer, who was only 48, was responsible for advances in the science of hæmatology, especially from the morphological standpoint. Although dangerously ill—he suffered from progressive tuberculosis of the larynx and lungs—he was continuing his researches on parenteral albumen, and on the action of peptonates, especially as a styptic in hæmoptysis, when his death occurred.

## The Services.

### ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. Whelan is placed on Retd. List.

Surg. Comdr. R. Kennedy is placed on retd. list with the rank of Surg. Capt.

#### ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lt. G. E. Spero to be Surg. Lt.

### ROYAL ARMY MEDICAL CORPS.

Lt.-Col. D. L. Harding retires on retd. pay.

Maj. J. M. M. Crawford to be Lt.-Col., vice Lt.-Col. D. L. Harding.

Maj. O. W. McSheehy to be Bt. Lt.-Col.

#### ARMY RESERVE OF OFFICERS.

Lt.-Col. G. O. Chambers, retd., to be Lt.-Col.

Maj. J. Vallance, retd., to be Maj., and Maj. C. J. H. Sharp, late Temp. Capt., R.A.M.C., to be Maj.

#### TERRITORIAL ARMY.

Capt. W. J. H. Davies, having attained the age limit is retd., and retains his rank.

### INDIAN MEDICAL SERVICES.

Kundan Lall Jetly to be Temp. Lt.

Capt. Pirojsha Merwanji Antia is transferred to the temp. non-effective list.

The Government of the Central Provinces invite applications from Indian or Anglo-Indian women graduates for a State Scholarship of £300 per annum, plus 7½ per cent. bonus, tenable in the United Kingdom or foreign countries. The scholarship will be awarded for study or medicine or other professions, and will be tenable for three years in the first instance with the possibility of extension. The services of Capt. G. R. McRobert, Wazerestan District, are temporarily placed at the disposal of the Government of Burma. Lt.-Col. G. Macpherson, professor of ophthalmology in the Grant Medical College, has returned to India from long leave.

### DEATHS IN THE SERVICES.

Fleet Surg. Alexander George William Bowen, R.N., retd., who died on Jan. 4th at Plymouth, aged 62, joined the Royal Navy as surgeon in 1891, and served in the gunboat *Partridge*, in the West Indies, and at the Plymouth Division, Royal Marines. He became staff surgeon in 1899, and in 1901 served in the sloop *Beagle* on the Cape and West Africa stations. Later he joined the cruiser *Amethyst* in the Atlantic Fleet, and in 1907 the battleship *Canopus*, when he was promoted to fleet surgeon. He also served in the battleship *Agamemnon*.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 2ND, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 203 (last week 178); scarlet fever, 1985; diphtheria, 1069; enteric fever, 44; pneumonia, 1807; puerperal fever, 55; cerebro-spinal fever, 4; acute poliomyelitis, 2; encephalitis lethargica, 32; dysentery, 8; ophthalmia neonatorum, 93. The figures in nearly every case are substantially greater than those of the previous week, which, as we have already remarked, were reduced by the holiday season. There were no cases of cholera, plague, or typhus notified during the week.

Of the 203 cases of small-pox, 90 (last week 106) were reported from the county of Durham; 20 (last week 39) from the county of Derby; and 54 from the West Riding of Yorkshire, 48 of which occurred in Rawmarsh.

*Deaths.*—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, none from small-pox, 87 from measles, 10 from scarlet fever, 44 from whooping-cough, 53 from diphtheria, and 123 (previous weeks 85 and 132) from influenza. In London itself there were 11 deaths from measles, 22 from diphtheria, 20 from diarrhœa and enteritis under two years, and 27 from influenza.

"Audi alteram partem."

## FUNCTIONAL OR ORGANIC?

*To the Editor of* THE LANCET.

SIR,—Regarding the thoughtful article under this title by Dr. C. P. Symonds published in THE LANCET of Jan. 9th, may I be allowed to emphasise the important part played by the blood in the genesis of functional nervous disorders? It is of the utmost importance that the physician should fully realise the potent influence of the blood on the feelings (=the sensations and emotions). It would scarcely be an exaggeration to say that the entire range of morbid feelings, both sensory and emotional, may be produced by morbid states of the blood. Nothing better shows this than the great variety of morbid feelings which can be produced by drugs. The peri-neuronic lymph plays, as it were, upon the mind-organ, either upon the grey matter directly or upon the sensory end-organs—these constituting a species of psychic keyboard—and by virtue of its manifold and ever-changing constituents causes the feelings to be modified in an infinite variety of ways.

Bearing in mind how largely the feelings bulk in the mental personality—that pleasure and pain, happiness and misery, the sense of existence itself (panæsthesia as we may term it), are all compounded of feelings, remembering also the influence of the feelings on thought and on conduct, it will be seen how profoundly the whole mental fabric is influenced for good or ill through the blood. Consider, for instance, the influence of the blood on (*a*) the special sensations, (*b*) other sensations, (*c*) the appetites, (*d*) panæsthesia, (*e*) the emotions. (*a*) All the special sensations may be influenced through the blood: functional blindness may occur in uræmia, deafness, tinnitus, and giddiness in a variety of toxæmias. (*b*) Other sensations: pains, general or local, are common in the toxæmias of febrile diseases, such as influenza, neuralgia is common in anæmia, and has, indeed, been described as "a prayer for healthy blood"; headache and other morbid cephalic sensations (e.g., sensations of pressure, heaviness, lightness, bursting, burning, crawling) are common accompaniments of the morbid blood states resulting from disturbance of the endocrine function of the ovaries; headache is also a common feature of many different kinds of toxæmia, such as those of the specific fevers, uræmia, indigestion, and drugs; pruritus and other cutaneous dysæsthesias may result from morbid blood states; a feeling of fidgetiness and many other muscular dysæsthesias may accompany morbid blood states. (*c*) The appetites: thirst, hunger, erotism (e.g., the rut) are largely dependent upon the state of the blood; normal sleepiness is chiefly produced through the blood, and the influence of the hæmic factor in this direction is also observed in the drowsiness of indigestion and the torpor of fever. (*d*) Panæsthesia: Seeing that individual sensations are profoundly influenced by the blood, it follows that the panæsthesia, which is a compound of them, is equally susceptible to hæmic influence. There is abundant evidence that the feelings of wellness and illness alike are delicately responsive to subtle changes in the blood. (*e*) The emotions: The influence of the blood on the emotions is equally profound. When the condition of the blood is such as to cause a pleasant panæsthesia pleasant emotions are apt to arise, and contrariwise as regards an unpleasant panæsthesia. It is probably not very wide of the truth to say that an intensely pleasant panæsthesia is incompatible with a downright unpleasant emotion, and, contrariwise, that an intensely unpleasant panæsthesia is incompatible with an acutely pleasant emotion. A pleasurable panæsthesia, especially the sense of exuberant well-being, tends to call forth joyousness and to foster a belief in self. It constitutes the fundamental psychic characteristic of the megalomaniac, whether as met with in everyday life or in the asylum. A painful panæsthesia in the shape of profound malaise tends, on the other hand, to evoke a feeling of gloom and self-distrust.

The blood may exercise a more specific influence on the emotional nature. Consider the apathy of the myxœdematous patient, the intense nervousness and agitation of the sufferer from Graves's disease, the violent emotionalism exhibited during the period of the rut, the altered emotional tone at the menstrual epoch and the climacteric, the irritability of the naughty child with the bad breath, or of the gouty man on the eve of his attack, the elation produced by alcohol, and the peculiar emotional effects of certain drugs, such as cannabis indica. No more striking instances of the effect of the blood upon emotionality could be adduced than those afforded by Graves's disease, the rut, and alcohol; the altered state of the blood in Graves's disease may change a calm, level-minded, self-disciplined, strong-willed woman into an excitable, agitated being, startled at the least noise and even by her own shadow, and incapable by any effort to control the raging storm within her. At the period of the rut the animal becomes restless, excitable, and (though ordinarily perhaps quite docile) ill-tempered and even dangerous, ready to fight its rivals to the death. As regards alcohol its emotional effects are manifold; it may make a shy man bold, a reserved man expansive, a mild man combative, a depressed man gay, a surly man genial, a cold man ardent, a close man generous. There is, indeed, hardly limit to the emotional effects which may be produced by this and kindred substances. The essential clinical features of most minor mental disorders (psychasthenia, hysteria, borderland insanity) is a morbid emotional state, and I cannot doubt that the latter is chiefly due to a morbid state of the blood, in which disturbed endocrine function often plays a prominent part.

A person's emotional temperament is, in large measure at least, determined by his blood. The reason why one person feels habitually well and in good spirits and another poorly and depressed is not so much because the mind instrument is in the one case specially adapted for mirthful music and in the other for minor harmonies, as because it is differently played upon by the blood in the two cases. It is scarcely an exaggeration to say that if two persons were to exchange bloods they would at the same time exchange temperaments. We are, I think, bound to conclude that individual differences in mental temperament are largely determined by differences in the compositions of the blood. And just as the habitual emotional note which we term mental temperament is largely influenced by the blood, so also are those transient changes in it from day to day and hour to hour which we term moods. Our moments of spontaneous depression result in the main from the action of depressants; our spells of exuberant well-being, of exhilaration, self-assurance and vaulting ambition, when all the world seems fair and no obstacle too great to surmount, no goal too difficult to win, are due to mild auto-intoxication produced by blood stimulants. May not genius owe its spells of inspiration to their influence?

As regards the influence of the psychogenic factor in neuroses and psychoses, it has to be remembered that psychic traumata, whether in the form of severe shock or petty household worries, by disordering metabolism, tend to vitiate the blood, thus setting up a vicious circle. The great desideratum for the nervous patient, indeed for all of us, is to cultivate the tranquil mind.

I am, Sir, yours faithfully,

Harley-street, W., Jan 9th, 1926. HARRY CAMPBELL.

---

## IDIOPATHIC RISE OF TEMPERATURE

*To the Editor of* THE LANCET.

SIR,—Your Paris correspondent recently gave (THE LANCET, Dec. 26th, 1925, p. 1357) a report of Dr Remlinger's communication to the French Academy of Medicine on this subject. The syndrome is, I think, the same as that described by me in 1920 as "continuous fever of sympathetic origin" (*Annales de*

*Médecine*, 1920, vii., 450). The only difference consists in the longer duration of the rise of temperature in my own cases. For weeks, for months, for years even, our patients showed elevation of temperature for which no cause could be found, no tuberculosis, no general infection, no focal infection. Temperature subsided when patients ceased to worry over it or to use the thermometer; it subsided also with rest, removal to a cool country, and various psychotherapeutical measures. The characteristic feature in my cases was an evidence of intense excitability of the sympathetic system detected by various pharmacological tests.

I attributed this "constitutional hyperthermia" to an inherent instability of the heat-regulating centre which, as is generally admitted, is part of the sympathetic system. On account of this instability there is a lowering of the threshold of the factors which raise normal temperature such as fatigue and emotion. I remarked that this instability of the thermic centre may be dependent on the chemical regulating organs of body heat, that is on the endocrines. It would be interesting to me to know if this syndrome is met with in England. I am of Dr. Remlinger's opinion that climatic factors play a great rôle in its appearance; in Greece the syndrome is met with more frequently in the hot months. It is of common occurrence in Greece. During the war, as consulting physician to the Greek army, I often had difficulty in distinguishing this "sympathetic fever" from tuberculosis.—I am, Sir, yours faithfully,

A. P. CAWADIAS, M.D., M.R.C.P.,
Senior Physician and Lecturer for Clinical Medicine,
Jan. 5th, 1926. Evangelismos Hospital, Athens.

## LAND REFORM AND SLUMS.

*To the Editor of* THE LANCET.

SIR,—Housing is one of the greatest medical problems. The housing of the people is much behind the requirements of the day, and large numbers are still very badly housed. Go to places like Becontree in Essex and Yardley or Stechford, suburbs of Birmingham, where houses for the working classes have been put up by the thousand in the last few years, and see them. It is true they have generally provided quarters which are far superior to those which many of the occupiers had to inhabit previously. But measure their capacity, inquire what is their rent, taking into account the expense of travelling to and from the place of work, examine the qualities they possess for enduring. Compare these little houses or flats—hundreds of them only three-roomed—and the materials used in them with some of the many small houses of Georgian or early Victorian days, or with little country cottages still in use, put up two or three hundred years ago. Ask any architect who has built for the well-to-do, and also participated in one of these schemes for housing the workers, what are his feelings on the cheese-paring, cost-cutting, cold and calculated restrictions which are imposed before they are erected, restrictions unfortunately necessary under present circumstances. Such comparisons bring the conclusion that what are built to-day will be looked upon as meagre and mean within a generation.

But what about the real slums now existing, and what about present-day overcrowding? Will the schemes of the Liberal Land Committee, should they come to fruition, really end these evil things soon? Is it on the right track to make a clear distinction between urban and agricultural land? To-day, both in law and in every-day practical usage, the distinction is ever arbitrary and changing. The latest available returns show over 14,000 condemned houses still in occupation, and condemnations are lenient. Although roughly half a million houses have been completed since 1919, that does not make up for the previously existing shortage, and the present rate of construction is in many cities insufficient to cope with the rate of increase of population. Manchester, for example, has an admitted shortage of 20,000 houses now, yet is to build only about 2000 a year. In Scotland there is an accumulated deficit, it is calculated, of 150,000 houses, the annual requirements of the country are about 10,000; yet in the year 1925 it is expected that not more than 8500 will have been finished. In the county of Durham only about 10,000 houses altogether have been built since the end of the war, during which period an increase of population of approximately 70,000 has occurred.

The idea of the garden city was put forward by Charles Kingsley as long ago as 1857. Yet to-day there are actually only two garden cities in existence, not counting Port Sunlight and Bournville. The clearance of the notorious London slums in the Tabard-street and Bradey-street areas began over 30 years ago. Yet to-day in neither area is the clearance by any means complete. Since the London County Council began it has spent over £1,000,000 on slum clearances. To be a measure of public health any scheme of land reform must bring about quicker results than these. It seems improbable that any scheme can succeed which lays an increasing burden upon the public purse, and does nothing to diminish costs or to increase wages and the number of building operatives. By applying tests of this sort the value can be appraised of any reform purporting to be a measure likely to improve the public health.

Let us hope that the Liberal Land Committee's plans will pass these tests. The Committee has worked hard and has set forth the subject with frank breadth of view, grasp of essentials, and a wealth of detail which is wholly admirable. But the remedies suggested seem complicated to the uninitiated and are, apparently, not satisfying to the party's supporters. Mr. Lloyd George himself, with characteristic skill, has assumed the power to give the people of England better housing, a more spacious life if only his remedies are adopted. He sincerely regards his land campaign as a public health measure. But many doctors have contracted the habit of examining with caution the plans of politicians, and it would be well to investigate afresh the whole subject of the connexion between land reform, better housing, and public health. If that is done much good will accrue. Should the Liberal Land Committee's plans be found to pass the suggested tests, there is no reason why they should not be taken up irrespective of party.

I am, Sir, yours faithfully,
LUCIUS SEVERUS.

## EMETINE IN THE TREATMENT OF HEPATIC ABSCESS.

*To the Editor of* THE LANCET.

SIR,—With reference to the article on this subject by Dr. P. H. Manson-Bahr and Dr. R. M. Morris in your issue of Jan. 9th, I think the following opinions of Dr. Manson-Bahr should be quoted. In the *Tropical Diseases Bulletin* for January and April, 1925, Dr. Manson-Bahr accepted the accuracy of Captain Fry's diagnosis without demur, although he now finds the records not very convincing. As regards treatment; in the *Bulletin* for January, 1925, Dr. Manson-Bahr says: "Surgeons should make the use of emetine an essential part of pre-operative preparation, *if not the sole treatment of liver abscess* . . . . It would appear that aspiration could be dispensed with in many such cases of amœbic abscess." And in the *Bulletin* for April, 1925, he states that "he has recently confirmed the view that emetine therapy alone can promote absorption of pus from a liver abscess without surgical interference. . . . In a recent case the patient developed a fourth abscess, three having been drained, *the very pronounced physical signs and symptoms of which were resolved in a short time by emetine combined with E.B.I.*" (The italics in both cases are mine.) The opinions given in your current number and those just quoted are completely contradictory, and one is left guessing as to the cause which, after Dr. Manson-Bahr had advanced from scepticism to understanding, has prompted this public confession of his return to his first state of mind.

I am, Sir, yours faithfully,
London, Jan. 11th, 1926. V. S. HODSON.

## STETHOSCOPY OF THE HEART.

*To the Editor of* THE LANCET.

SIR,—Dr. Otto May's denunciation of the dangers of stethoscopy should not have been directed at the general practitioner, but at the teachers in medical schools for misdirecting their students as to the cause of the sounds associated with the movements of the heart. For nearly 100 years it has been taught that the first sound of the heart is due mainly to contraction of the heart muscle, whereas it is known that a muscle when it contracts produces no sound. The second sound is said to be due to the banging together of the cusps of the valve, yet if they be eaten away by disease the sound is magnified into a marked murmur. If the cause of the heart sounds be not known, how can the cause of their modification be properly assessed?

I am, Sir, yours faithfully,

Swansea, Jan. 11th, 1926. G. ARBOUR STEPHENS.

## THE VENTILATION OF ENGINE-ROOMS IN MOTOR VESSELS.

*To the Editor of* THE LANCET.

SIR,—In view of the enormous increase in the proportion of tonnage now fitted with motors, and the still higher proportion probable in the future, I venture to bring forward a human aspect in their respective economics which may have far-reaching consequences. I refer to the injurious effects I have noticed of the vapours, inseparable from the Diesel and similar motors, upon the engine-room staffs. These are so obvious that at the end of a voyage anyone could separate with accuracy the engine-room staff of a motor vessel from that of a steamship. Not all are equally affected, but an occupation which causes headache, drowsiness, vomiting, loss of appetite, an evident pale yellow tinting of the skin, and a great susceptibility to an obstinate type of furunculosis, is likely to have a permanent ill-effect upon the strongest constitution in time.

The obvious cause is inadequate ventilation, but the prevention is anything but simple. In the ordinary way ships are more difficult to ventilate than any building, and here a super-excellent scheme is necessary. In the meantime motor vessels are being constructed with more or less the same ventilation as exists in the engine-rooms of steamships, which falls far short of the motor vessels' requirements. At present air is propelled by fans from outside into the engine-room and heated if necessary, as it must be hot because the intake of air for the cylinders is directly from the engine-room itself. The vitiated air from the engine-room with the vapours escapes through the skylights and the exit ventilators, their efficiency depending upon the wind speed caused by the motion of the vessel. The vapours are densest when the vessel is manœuvring in port, and at this time the ship's speed is at its lowest. In every engine room, moreover, there are numerous obstructions to the free movement of the air, such as tanks and orlop decks, which act as baffle-plates and cause pockets of stagnant air. The escape for the fumes from the crank case, which are particularly evil-smelling, opens directly into the engine-room instead of outside. The engineers themselves are partly to blame because they invariably leave the small cock on the exhaust from each cylinder open, so that any cylinder misfiring can be detected at once. There are many other defects, but these serve to illustrate the conditions existing.

I suggest that the whole question of the ventilation of the engine-rooms of motor vessels requires careful consideration, as I am convinced that the present conditions are definitely adverse to the health of the engineers.

I am, Sir, yours faithfully,

A. G. G. THOMPSON, M.D.,

Assistant M.O.H., Liverpool Port Sanitary Authority.

Jan. 11th, 1926.

# Obituary.

## JOHN GRAY McKENDRICK, M.D., LL.D. ABERD., F.R.C.P. EDIN., F.R.S.

THE death of Prof. J. G. McKendrick at Glasgow on Jan. 2nd removes a man who helped to lay the foundations of modern physiology and in whose life character and ability were wholly responsible for success.

John Gray McKendrick was born at Aberdeen in 1841. He was early left an orphan and spent his school days at Braco, in Perthshire, where, at 13, during a long summer, he herded sheep from 5 in the morning until 8 at night. At 14 he entered the office of a lawyer in Aberdeen, to whom he was apprenticed at a pittance; for nearly two years his landlady managed to feed and clothe him for *5s. 6d.* a week. In spite of long hours at the office he began an elaborate course of home study; he was a good swimmer, played cricket, and spent his annual two weeks' holiday at Braco helping in the harvest. A great love of Nature led him to collect plants and marine animals along the shores of the Bay of Nigg, and he started a little aquarium which evidently brought him some repute, as he was asked to show it at the British Association meeting in 1859, when the Prince Consort was chairman. There he saw Gould, Richard Owen, Huxley, Roderick Murchison, and Faraday; already science had begun to call him. Rising often at 5 A.M. and working till his office opened at 10, McKendrick passed the Medical Preliminary at Aberdeen in 1861. Dismissed by his lawyer master because he dallied at a concert where Jenny Lind was singing, he moved to Edinburgh, entered the classes in anatomy and natural history, and eked out a living by working eight hours a day for the *Daily Review* at 12s. a week. "The hours at the University," he said, "were the delightful part of the day. They made up for all the drudgery." Yet the teaching and examinations of that time were far from satisfactory. There were no practical classes, few demonstrations, and no familiarity with apparatus. "But," wrote Prof. McKendrick, "there was a sound knowledge of general principles and a strong belief in one's self. In Edinburgh there were no fewer than seven theories of inflammation in vogue amongst the examiners!" At Edinburgh he heard Goodsir lecture and saw Turner and Joseph Bell demonstrate. His teachers were amongst the giants of those days: James Miller, the surgeon, Simpson and Syme, whose controversy was at its height, and Laycock in the chair of medicine.

McKendrick's struggles were pathetic—but he took Goodsir's medal in 1863, and was a prizeman in surgery, obstetrics, and medicine, though zoology remained his favourite study. In 1864 he graduated as M.D., with distinction, at Aberdeen, and after some months at the infirmary at Chester, where he saw 200 cases of small-pox, became surgeon to the Eastern Dispensary at Whitechapel, where patients were dealt with at the rate of one every two minutes. This did not attract him, and he was always on the look-out for other work, applying for the post of prosector at the Zoological Gardens, a practice in Sark, a job on a tea plantation in Assam, and work in Earlswood Asylum. At last he was placed on a short list of 87 candidates for a house surgeon appointment at Fort William, and having told the trustees that he was "brought up in the Established Church; but when I came to the years of discretion, I joined the Free Church," was given the post. In Fort William he spent four happy years, giving his first lectures on scientific subjects to the people around; here he joined the Volunteers, and here in 1865 he married Miss Mary Souttar, of Aberdeen.

In 1869 McKendrick by happy chance met Hughes Bennett and went to Edinburgh as his assistant; his duty was to teach the subject of histology, then recently introduced. Amongst his students were Miss Jex-Blake, Sir William Watson Cheyne, Prof.

Cash, Prof. Ewart, and Sir George Beatson. Here he lectured to the first physiology class wholly composed of women. Disappointed of the chair of physiology on Bennett's retirement, McKendrick offered a course of 40 lectures to women only, and 150 of them enrolled. Soon afterwards he met James Dewar, who suggested coöperation in the research which led to the discovery that an electric current is produced in the optic nerve when light falls on the retina. This work was published in 1873; for the first time a current of action had been demonstrated in a sensory nerve as the result of the normal stimulation of its end organ. Holmgren, of Upsala, made the observation independently almost at the same time. Dewar and McKendrick later investigated the physiological action of chinoline and certain pyridine bases, and this work was amongst the first research which correlated chemical constitution and physiological action.

In 1872 McKendrick was elected F.R.C.P. Edin., and in the same year visited Germany and made the acquaintance of Helmholtz, whose memory he ever afterwards revered and whose life he wrote. Then, in 1876, came his appointment as Professor of Physiology at Glasgow, which he held until 1906. He found a lecture room, a sphygmograph, a few old microscopes, and some diagrams; on these he built up the department of physiology which preceded the present institute. He was the most pleasing of lecturers, and in 1881 was appointed Fullerian Professor of Physiology at the Royal Institution, where he gave Friday evening discourses and Christmas lectures to children. In 1884 he was elected Fellow of the Royal Society, and later served on the Council, holding also numerous university examinerships.

Prof. McKendrick's written works have the same pleasant flavour as his spoken words. To the Encyclopædia Britannica he contributed much, and in 1878 published "Outlines of Physiology," followed ten years later by a "Text-book of Physiology." Conjointly with one of his assistants, Dr. William Snodgrass, he produced "The Physiology of the Senses"; physiological acoustics had always interested him especially. He also published poems, and his love of music and poetry contributed largely to his singularly attractive personality. A savant and a physician, he was also a real naturalist in the sense given to that term by his friend Sir William Gairdner, "a humble, reverent, and exact follower and student of Nature." A man of distinction himself, he was privileged, as he said, to count Lord Kelvin, John Caird, and Lord Lister among his friends.

Prof. McKendrick's wife died some years ago. He is survived by two sons, Dr. J. Souttar McKendrick, of Glasgow, and Dr. Anderson McKendrick, of the Royal College of Physicians' Laboratory, Edinburgh, and late colonel in the Indian Medical Service; and also by a daughter, the wife of Dr. A. A. Warden, of Cannes. His other daughter, who was married to the Rev. R. Bruce Taylor, Principal of Queen's University, Kingston, Ontario, died some months ago. He was buried on Jan. 6th in the family vault in Cowie Churchyard at Stonehaven. It was at this little fishing town overlooking the North Sea that Prof. McKendrick used to spend his summer holidays, and it is largely to his influence that it owes its popularity.

## JOHN BARTHOLOMEW GILES GIDLEY-MOORE, L.R.C.P. LOND., M.R.C.P. EDIN.

Dr. Gidley-Moore, who died last week at his residence at Fyfield House, near Ongar, was a familiar figure locally as medical officer of health, ambulance instructor, and member of the board of guardians. He qualified in 1872 from St. George's Hospital and spent 35 years in country practice; his retirement from active work of this kind was only the occasion for greater activity in other spheres, for he was chairman, treasurer, and correspondent of the parish schools, vice-chairman of the parish council, and an original member of the Essex Insurance Committee. Dr. Gidley-Moore was held in respect for his strong views on social matters which he held irrespective of personal advantage. To uphold the principle of individual thrift he would accept no superannuation for himself or sanction it for others, and he was an influential member, sometime vice-president, of the Poor-law Medical Officers' Association. In his ambulance work he ultimately became senior surgeon of No. 1 Division and held both Diamond Jubilee and Coronation medals for long service.

## GERALD GODFRAY GIFFARD, K.C.I.E., C.S.I., M.R.C.P. LOND., M.R.C.S. ENG.

With the death in London on Jan. 5th of Major-General Sir Gerald Giffard, on the eve of his sixtieth year, the Indian Medical Service loses one of its most distinguished and many-sided officers.

Gerald Godfray Giffard was born in Guernsey on Jan. 19th, 1867, the son of Mr. Agnew Giffard, resident engineer of the harbour works, who was drowned off Sark in the following year, and a nephew of Sir Henry Giffard, K.C. He was educated at Elizabeth College, Guernsey, and studied at St. Bartholomew's Hospital, qualifying with the conjoint diploma in 1889, and taking the M.R.C.P. a few years later. In 1890 he entered the Indian Medical Service, becoming captain in 1893, major in 1902, lieut.-colonel in 1910, and major-general in 1918. He accompanied the Chin Hills and Manipur Expeditions, and being a keen and hardworking officer was marked early for promotion and was translated to Madras in 1897 as resident surgeon to the General Hospital. He became district medical and sanitary officer at Chingleput, and in 1901 was appointed to his first chair in the Madras College, that of materia medica. During the following years he filled in succession the chairs of surgery and midwifery, with the added responsibility of directing the Government Maternity Hospital at Madras. By this time he had become known as a skilful surgeon and gynæcologist as well as a sound practical teacher of midwifery, and it was largely owing to his initiative and persistent effort that Madras came into possession of the finest and best equipped children's hospital in the East. As principal of Madras Medical College he was responsible for numerous improvements in its organisation and work. During the war Giffard filled a number of important positions. In 1915 he was in command of the Madras Field Hospital Ship, a highly organised and elaborately equipped institution with a brilliant medical staff chosen from the Madras Medical College. In those days, now happily forgotten, Giffard was one of the first to recognise the shortcomings of the medical field organisation and used his influence to foster the inquiry of the Mesopotamia Commission which followed in 1917. This inquiry was doubly welcome to him, for it was the means of altering the whole attitude of the Government towards the medical requirements of the army in India. Giffard was transferred to the Northern Command in 1917, when he controlled the large Indian general hospital at Rawalpindi until his selection (at an unusually early age) as surgeon-general with the Government of Madras took him back to the scene of his earlier work.

Sir Patrick Hehir, who was associated with him in one way or another for over 35 years, appraises Sir Gerald Giffard as an administrator with a well-balanced mind and a wide grasp of the many complex and conflicting medical problems that beset statesmen in India. "One of my most pleasant recollections," writes Sir Patrick Hehir, "is the fine tone that existed in the whole of the Madras Medical Service when I visited that city in 1918. Giffard seemed to me to be the Little Father of a large and capable medical family. We worked together on the Medical Services Committee to which Giffard was a tower of strength. One of his last great efforts was to get the Madras Government to subsidise private medical men to go into practice in rural areas. Had this policy taken effect throughout India, it would, within a decade, have altered for the better the whole aspect of the medical care of the indigenous masses. Giffard was a fine personality, a deep and clear thinker, a bold and courageous medical administrator, a true and reliable friend, and a most cheerful companion. In his passing many like myself have lost a valued friend."

After his return from India Sir Gerald Giffard retired to Guernsey, living at Lafosse, St. Martin's, where he became honorary medical superintendent to the Lady Ozanne Maternity Home and general secretary to the local branch of the League of Nations. Sir Gerald Giffard married in 1898 Melicent, eldest daughter of James Grose, C.I.E., I.C.S., by whom he had two sons and two daughters.

## WILLIAM NETTLE, M.R.C.S. ENG., J.P., V.D.

Dr. Nettle's death at Liskeard at the age of 77 years removes a well-known Cornish practitioner who had throughout a long life taken his full share in all phases of public life. Born near St. Austell, he was apprenticed when still in his teens to Dr. Alfred Prideaux, a Bartholomew's man, so that it was natural for young Nettle, in his turn, to do his medical study at St. Bartholomew's, qualifying from there in 1870 and returning—after a resident appointment at the Royal Cornwall Infirmary, Truro—to join Dr. Prideaux in partnership. Not long afterwards he married Kathleen Vivian Prideaux, his partner's third daughter, and succeeded later to the whole of a large practice. In his later years of practice Dr. Nettle was also medical officer of health for the borough and rural district of Liskeard, surrendering for this purpose his seat on the town council, of which he had been a member for ten years and mayor on four occasions. During the last few years of his life he was a member of the board of guardians and for a long time he was both county and borough magistrate. As a Churchman he stood for progress; he was vicar's warden for 33 years and a regular sidesman. He was a member of the Masonic order for more than 50 years and actively espoused the cause of Masonic charities. His connexion with the Volunteers began with a surgeon-lieutenancy to the 2nd Volunteer Brigade and he ultimately became P.M.O. to the Devon and Cornwall Infantry Brigade, retiring with the honorary rank of Lieut.-Colonel R.A.M.C. About six months ago he had a seizure from which he never completely recovered. He leaves a widow, a married daughter, and five grandchildren.

THE LATE DR. ALEXANDER DICK.—Dr. A. Dick, who died at his house at Llanelly on Dec. 27th, was 47 years of age and had been in poor health for some time. He was born in County Down and was educated at Queen's College, Belfast, and Edinburgh University, taking the Scottish triple diploma in 1905. Soon afterwards he went into an assistantship at Llanelly; then he moved to Cardiff, but returned later to Llanelly, which he did not leave again except on war service. For several years he held a captain's commission in the Royal Army Medical Corps, being attached to the 4th Welch Territorial Battalion. Dr. Dick was a prominent Freemason. He was a popular and genial man, whose happy disposition brought him many friendships. He leaves a widow and three children.

DONATIONS AND BEQUESTS.—Towards the appeal for £500,000 for the reconstruction and development of the University of Leeds, launched in October, 1925, during the past three and a half months £238,000 have been received.—The King, patron of the King Edward Hospital Fund for London, has sent his annual subscription of £1000 to the Fund.—Mr. George Travis, of Wardle, near Rochdale, left £1000 each to the Oldham Royal Infirmary and the Rochdale Infirmary, and £500 to the Memorial Homes for Crippled Children, Rochdale.—Mr. Thomas Brett Daniell, of West Bergholt, Essex, who left estate of the value of £15,080, left a bequest of £500 to the Royal Eastern Counties Association and many legacies, and the residue to his sister for life, and at her death, after the payment of certain bequests, the ultimate residue between the Royal Eastern Counties Association for Idiots, the Essex County Hospital, Colchester, and Arthur Winsley's Charity, Colchester.

# Medical News.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were successful:—

M.D. EXAMINATION.

*Branch I., Medicine.*—Davis E. Bedford, Middlesex Hosp.; Frank Brockington, King's Coll. Hosp.; Gwenvron Mary Griffiths, London Sch. of Med. for Women; David Krestin, London Hosp.; James Maxwell, St. Bart.'s Hosp.; Alan A. Moncrieff and David C. Muir, Middlesex Hosp.; and Selwyn E. Tanner and Hubert N. Williams, Univ. Coll. Hosp.

*Branch III., Psychological Medicine.*—Alexander Walk, St. Bart.'s Hosp.

*Branch IV., Midwifery and Diseases of Women.*—Daryll C. Corry, Univ. Coll. Hosp.; and Gladys Hill and Dorothy M. Howgate, London Sch. of Med. for Women.

*Branch V., State Medicine.*—Joseph V. Landau, St. Bart.'s Hosp. and Univ. Coll. Hosp.

A course of six lectures on the Physiology of Reproduction will be given by Dr. A. S. Parkes at University College on Jan. 18th and 25th, Feb. 1st, 8th, 15th, and 22nd, at 5.30 P.M.

A course of eight lectures on Metabolism of Carbohydrate and Fat will be given by Dr. J. A. Hewitt, at King's College, on Jan. 21st and 28th, Feb. 4th, 11th, 18th, and 25th, and March 4th and 11th, at 5 P.M. Admission is free without ticket.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

MASTER OF HYGIENE.

*First Examination, Part II.*—B. L. Davis.

DIPLOMA IN PUBLIC HEALTH.

*Part II.*—G. L. Brocklehurst, C. Cookson, A. O. Ross, and C. H. Walsh.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—On Jan. 18th and on the following Monday, Wednesdays, and Fridays, until Jan. 29th, Sir Arthur Keith will give a series of six lectures at the College, at 5 P.M. each day, on Fossil Remains of Apes and Man, and their Bearing on the Evolution of Human Races. The lectures will be illustrated by preparations from the museum and by lantern slides. On Jan. 18th he will discuss the Anatomical Characters of the Galilee Skull.

TUBERCULOSIS SOCIETY.—Following an address on Tuberculosis in Wales, by Prof. Lyle Cummins, at 1, Upper Montague-street, Russell-square, London, W.C., at 8 P.M., on Jan. 15th, there will be an opportunity for members of the society to attend the annual meeting of the Society of Superintendents of Tuberculosis Institutions on Monday, Jan. 18th, at 3 P.M. The meeting will be held at 122, Harley-street, London, W., and there will be a discussion on Occupational Therapy, in which papers will be read by Dr. J. E. Chapman, Lieut.-Colonel J. R. Lord, Mrs. Kimmins, of the Heritage Craft Schools, Chailey, Dr. Jane Walker, and Dr. Esther Carling. Dr. Lucas Hammond will read a paper on Phthisical Psychology.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Dr. Herbert Spencer will give the opening lecture of the new series, arranged by the Fellowship and free to members of the medical profession, on Thursday, Jan. 21st, at 5 P.M., in the lecture hall of the Medical Society, 11, Chandos-street, London, W. Dr. Spencer will speak on Abdominal Palpation in Pregnancy (with lantern demonstration). A comprehensive course in Venereal Diseases will begin at the London Lock Hospital on Feb. 1st and continue till Feb. 27th. There will be instruction in the out-patient department and lectures on different aspects of the diseases. At the Blackfriars Hospital for Diseases of the Skin an afternoon course in Dermatology will be held from Feb. 1st to 8th. A three weeks' combined course in Diseases of Children will be given from Feb. 8th in which the Paddington Green Children's Hospital, the Victoria Hospital, and the Children's Clinic will participate. There will be morning and afternoon sessions held in all the various departments of the hospitals. A late afternoon course (4.30 to 6) will take place at the London Temperance Hospital from Feb. 8th to 19th for the convenience of the general practitioner. Queen Mary's Hospital, Stratford, will give a general intensive course in medicine, surgery, and the special departments from Feb. 15th to 27th. Daily sessions will be held from 10.30 A.M. to 5 P.M., including demonstrations of clinical methods and groups of illustrative cases. A special feature of the course will be the opportunity for the practical study of gynæcology and obstetrics. A copy of each syllabus of the foregoing courses and of the programme of the General Course may be had on application to the secretary of the Fellowship, 1, Wimpole-street, London, W. 1.

Gloucestershire Royal Infirmary.—This hospital is to be enlarged by the addition of an eye department and a laundry, at a cost of £12,000.

Nationalisation of Hospitals.—An address on this subject will be delivered to-day (Friday) at the headquarters of the Incorporated Association of Hospital Officers, 28, Bedford-square, London, W.C., by Mr. Somerville Hastings, F.R.C.S., at 7.30 P.M.

Medico-Legal Society.—A meeting will be held at 11, Chandos-street, Cavendish-square, London, W., on Jan. 19th, at 8.30 P.M., when a paper read by Dr. Godfrey Carter and Dr. Herbert W. Southgate on the Excretion of Alcohol in Urine as a Guide to Alcoholic Intoxication will be followed by a discussion.

Lord Ampthill, for many years chairman of the Central Committee for the State Registration of Nurses, was recently presented with a specially bound copy of the State Register of Nurses in recognition of his services to the nursing profession. The presentation was made by Mrs. Bedford Fenwick, the secretary of the committee, with whose name Lord Ampthill said the register would always be associated.

The Voluntary Hospital System.—The Adelphi Literary and Social Circle has arranged a debate on a motion by Mr. A. S. Coombes, that the Voluntary Hospital System has proved Inadequate to the Needs of the People, which will be held on Tuesday, Jan. 19th, at 8 P.M., in the ballroom of the Lyceum Club, 138, Piccadilly, London, W. Councillor Mrs. Lionel Harris will preside and Mr. Gilbert G. Panter, secretary of the Royal Northern Group of Hospitals, will oppose the motion.

National Memorial to Queen Alexandra.—The scheme for the Queen Alexandra National Memorial Fund for the assistance of Queen Victoria's Jubilee Institute for Nurses was inaugurated by a meeting at the Mansion House, London, on Thursday of last week, under the chairmanship of the Lord Mayor. It was announced that £10,500 had already been subscribed, and it is understood that considerable additional donations have since been received. A small portion of the total is to be devoted to a " visible memorial " of Queen Alexandra.

Royal Institution.—On Tuesday, Jan. 19th, at 5.15 P.M., Prof. J. A. Crowther will give the first of two lectures at the Royal Institution, on X Rays and Living Matter. On Thursday, Jan. 21st, at the same hour, Prof. C. J. Patten will give the first of two lectures on the Language of Birds and the Breeding Factor in Birds; and on Saturday, Jan. 23rd, at 3 P.M., Mr. Henry Balfour will lecture on the Evolution of Coinage. The Friday evening discourse on Jan. 22nd will be delivered by Sir William Bragg on the Work of the Davy Faraday Research Laboratory, and on Jan. 29th by Sir William B. Hardy on Films.

Lectures on Infant Care.—A course of lectures on infant care, especially intended for creche nurses and probationers, will be given in the lecture hall, Carnegie House, 117, Piccadilly, London, W., on Thursdays, at 7.30 P.M., from Jan. 21st to March 25th. The lecturer will be Dr. Victoria Bennett, and the subjects of the first three lectures will be Duties to the New-born Baby, Natural Feeding, and Artificial Feeding. The course is in preparation for the Creche Nurses' Advanced Certificate, granted by the National Association for the Prevention of Infant Mortality and the National Society of Day Nurseries, and an examination will be held at the end, on March 27th. The fee for the ten lectures will be 10*s.*, or for any single lecture 1*s.* 3*d.*, and tickets may be obtained from Miss Maddock, 117, Piccadilly, London, W. 1.

Presentation to Prof. Rutherford Morison.—At the end of 1921 a movement was started amongst members of the profession to commemorate the work of Emeritus Professor Rutherford Morison, of Newcastle. It was decided to appeal to the profession for subscriptions to present Prof. Morison with his portrait in oils, and after defraying the cost of the portrait to devote the balance either to the formation of a medical library fund or the establishment of a scholarship or fellowship in research, or such other objects as Prof. Morison might approve. In June last we published the third list of subscriptions, which amounted to £1528. It is now announced that the portrait, painted by Mr. Harold Knight, will be presented to Prof. Morison on behalf of the subscribers by Prof. H. Brunton Angus at the College of Medicine, Newcastle-on-Tyne, on Thursday, Jan. 21st, at 4 P.M. It is hoped that as many subscribers as possible will

Middlesex Hospital Rebuilding Fund.—The rebuilding fund of the Middlesex Hospital now stands at £273,000, having risen from £216,000 in less than a month.

Princess Mary Viscountess Lascelles is to lay the foundation-stone of the extension of the Royal Infirmary, Sunderland, on Feb. 17th.

Post-Graduate Course at Sheffield.—A course of clinical demonstrations open to all qualified medical practitioners without fee is to be held in Sheffield, mainly at the Royal Infirmary, from January to March. Particulars will be found weekly in our Medical Diary.

Hunterian Society.—The annual dinner will be held at the Hotel Victoria, Northumberland-avenue, London, W.C., on Thursday, Feb. 11th, at 7.30 P.M. Applications for tickets may be sent to Mr. A. E. Mortimer Woolf, 94, Harley-street, London, W. 1.

A further application by Dr. F. W. Axham to the Royal College of Surgeons of England for the return of his diploma is receiving the consideration of the Council. It will be recalled that Dr. Axham's diploma was forfeited in 1911 following the erasure of his name from the Medical Register on account of his association with Mr. (now Sir Herbert) Barker. The Royal College of Physicians of Edinburgh is also likely to consider the question of sending back its diploma to Dr. Axham.

Lighting of Coal Mines.—The next meeting of the Illuminating Engineering Society will be held at the house of the Royal Society of Arts, 18, John-street, Adelphi, London, at 7 P.M. on Thursday, Jan. 21st, when a discussion on the Lighting of Coal Mines will be opened by Mr. Eric Farmer, investigator to the Industrial Fatigue Research Board. Those interested are invited to apply for tickets to the Hon. Secretary, Mr. L. Gaster, 32, Victoria-street, London, S.W. 1.

Medical Officers of Schools Association.—The annual general meeting of this association is to be held on Friday, Feb. 5th, at 11, Chandos-street, Cavendish-square, London, W., when Dr. R. A. O'Brien, director of the Wellcome Physiological Research Laboratories, will read a paper on the Prevention of Diphtheria and Scarlet Fever by Modern Methods. If possible, reactions will be shown. Dr. O'Brien's paper is to be read at 5 P.M., following a business meeting at 4.15 P.M., and tea at 4.30 P.M.

Chelsea Clinical Society.—A meeting of this society will be held at the Florence Restaurant, 56, Rupert-street, London, W., on Tuesday, Jan. 19th, at 8.30 P.M. It will be preceded by dinner, commencing at 7.30 P.M.; members intending to dine should inform Dr. L. D. Bailey, 42, Eaton-terrace, London, S.W. 1. The price of the dinner will be 5*s.*, exclusive of wine, and guests will be welcome. After the dinner there will be a discussion on Heliotherapy, in which Dr. Leonard Hill, Sir Henry Gauvain, Dr. Henry MacCormac, and Dr. Howard Humphris will take part.

Small-pox in Yorkshire.—Although there are over 120 cases of small-pox in the rural area around Rotherham, the town itself, owing to the prompt steps taken by the health authorities, is almost immune. Only two cases have been reported. The Ministry of Health has warmly commended the Rotherham district authorities for their prompt diagnosis and isolation of all cases. Home contacts have been put into quarantine—usually for 24 hours—to permit of thorough disinfection of infected houses. Each contact has been kept under almost daily supervision for three weeks, and it is a striking fact that all contacts have accepted vaccination during the period of quarantine.

Psychology in the Nursery.—A series of six lectures for mothers, under the general title of Everyday Psychology in the Nursery, is to be given at Carnegie House, 117, Piccadilly, London, W., beginning on Feb. 17th, at 3.15 P.M., and continuing upon the Wednesdays following. The first lecture is entitled the Super-sensitive Child, and will be given by Dr. Mary Heming Rees, whilst the other lecturers will be Dr. Elizabeth Sloan Chesser on the Problems of the School-girl, Dr. Kenneth Dickson on Health and Character, Dr. Howard Humphris on Sunlight and Psychology, and Miss Alice Jackson on Children's Books. To end the series there will be a lecture by Dr. J. R. Rees on March 24th at 6 P.M., for fathers as well as mothers, which is to be called Some Problems in Family Adjustment. Further particulars may be obtained from the Viscountess Erleigh, 65, Rutland-gate, London S.W. 7, or Mrs. Ernest Shaw, 65, Conduit-street, W. 1.

POST-GRADUATE DENTAL COURSE.—A course of seven lectures is to be given at the Royal Dental Hospital of London, Leicester-square, W.C., on Jan. 20th, and the following Wednesdays until March 3rd, at 5.30 P.M. each day. The subjects of the first two lectures will be Mouth Breathing and the Mouth as a Focus of Infection. The remaining titles and the names of the lecturers may be found weekly in our Medical Diary. The lectures will be open to all who are interested, without fee or ticket.

INQUESTS IN SALFORD.—During 1925 Mr. A. Holmes, the Salford coroner, received notification of 306 deaths and 200 inquests were held. In 110 cases the verdict was "Death from natural causes." Six males and four females committed suicide by poisoning and in three other cases death was due to accidental poisoning. Four males were found drowned. Thirteen females and five males died following injuries received in the streets, and 13 males and 10 females succumbed to injuries after being run over. There were 16 fatal burning cases. Three women died through drinking in excess.

PEOPLE'S LEAGUE OF HEALTH.—A series of eight lectures on the *Mind and What We Ought to Know About It* will be delivered at the house of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., beginning on Feb. 1st, at 6 P.M. The following is a list of lecturers and subjects: *Sensation, Perception, Ideation, and Attention*, Dr. R. H. Cole; *Mind and Body*, Sir Frederick Mott, F.R.S.; *Association of Ideas, Recognition, and Memory*, Dr. Thomas Beaton; *Habit, Adaptation*, Sir Maurice Craig; *Crime and Delinquency*, Dr. W. A. Potts; *Fatigue and Sleep*, Dr. H. Crichton-Miller; *Primitive Instinct*, Dr. E. D. Macnamara; *Mental Deficiency*, Dr. A. F. Tredgold. Further particulars may be obtained from the offices of the League, 12, Stratford-place, London, W. 1

## Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

### SOCIETIES.

**ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**

**Tuesday, Jan. 19th.**

GENERAL MEETING OF FELLOWS: at 5.30 P.M.
Ballot for election to the Fellowship.
PATHOLOGY: at 8.30 P.M.
*Paper:*
Dr. Sidney Dickenson: A Simple Method of Isolating and Handling Individual Spores and Bacteria.

**Wednesday, Jan. 20th.**

*HISTORY OF MEDICINE: at 5 P.M.*
*Paper:*
Dr. Alfred G. Francis: On a Romano British Surgical Instrument, probably a Castration Clamp used in the Rites of Cybele.

**Thursday, Jan. 21st.**

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
*Cases will be shown.*
*Paper:*
*Prof. Levaditi*: New Discoveries in the Chemotherapy of Syphilis.

**Friday, Jan. 22nd.**

STUDY OF DISEASE IN CHILDREN: at 5 P.M. (*Cases at 4.30 P.M.*)
*Communication:*
*Dr. D. J. Hishon* (introduced by Dr. J. D. Rolleston): Gangrene of Legs following Measles (photograph).
*Cases will be shown.*
EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.
*Paper:*
Prof. E. W. Hope (Liverpool): The Influence of the Universities on the Advancement of the Public Health.

ROYAL INSTITUTION, Albemarle-street, W.
TUESDAY, Jan. 19th.—5.15 P.M., Dr. J. A. Crowther: X Rays and Living Matter.
FRIDAY.—9 P.M., Sir William Bragg: The Work of the Davy Faraday Research Laboratory.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish square, W.
*THURSDAY*, Jan 21st.—8.15 P.M., preceded by a Demonstration at 7.15. Dr. James Hasson will make an announcement on a New Procedure in the Diagnosis and Treatment of *Leprosy*. Lieut.-Colonel W. P. Macarthur, R.A.M.C.: An address on Old-Time Plague in Britain.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.
MONDAY, Jan. 18th.—3 P.M. (at 122, Harley-street): Discussion on Occupational Therapy, and papers will be read by Dr. J. E. Chapman, Lieut.-Colonel J. R. Lord, O.B.E., Mrs. Kimmins, Dr. Jane Walker, and Dr. Esther Carling. Dr. A. Lucas Hammond will also read a paper on Phthisical Psychology.

MEDICO LEGAL SOCIETY.
TUESDAY, Jan. 19th.—8.30 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. G. Carter and Dr. Herbert W. Southgate: The Excretion of Alcohol in Urine as a Guide to Alcoholic Intoxication.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
*MONDAY*, Jan. 18th.—5 P.M., Sir Arthur Keith: The Anatomical Characters of the Galilee Skull.
WEDNESDAY.—5 P.M., The Interpretation of Endocranial Casts from Skulls—Ancient and Modern.
FRIDAY.—5 P.M., Ancient Dwellers in the Thames Valley.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Jan. 18th, to SATURDAY, Jan. 23rd.—BETHLEM ROYAL HOSPITAL, S.E. Lecture-demonstrations in Psychological Medicine at 11 A.M. Tues. and Sat., Dr. Porter Phillips and Dr. Thomas Beaton: The Psychoses.—NORTH-EASTERN FEVER HOSPITAL, St. Ann's-road, Tottenham. Wed., 2.30 P.M., Sat., 11 A.M., Dr. Frederic Thomson: Demonstration in the Diagnosis and Treatment of the Acute Infectious Diseases.—LONDON HOSPITAL. Tues., 2 P.M., Special Clinical Demonstration by Mr. Souttar.—NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W. Intensive Course (first week).—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, N. Special course, daily lectures, and demonstrations.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Special course in the Diagnosis and Treatment of Common Diseases of the Nervous System. Lecture-demonstrations at 5 P.M. throughout the week.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Jan. 18th.—4.30 P.M., Prof. Hugh MacLean: Diabetes and Insulin in General Practice.
TUESDAY.—4.30 P.M., Dr. Frederic Thomson: Recent Advances in Scarlet Fever and Diphtheria.
WEDNESDAY.—4.30 P.M., Dr. P. Manson-Bahr: The Treatment of Dysentery.
THURSDAY.—4.30 P.M., Mr. W. E. Tanner: Chronic Abdominal Pain.
FRIDAY.—4.30 P.M., Dr. L. R. Yealland: Hysterical Fits.
Daily, 10.30 A.M. to 1 P.M., Demonstrations of Clinical Methods. 2 P.M., to 4 P.M., Groups of Selected Cases and General Hospital Work.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Jan. 19th.—5 P.M., *Dr. Knowsley Sibley*: Electro-therapeutics.
THURSDAY.—5 P.M., Pathological Demonstration.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.
WEDNESDAY, Jan. 20th.—5.30 P.M., Mr. A. L. Packham: Mouth-breathing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.
WEDNESDAY, Jan. 20th.—Dr. Harrison: The Tests of Renal Efficiency.
THURSDAY.—4 P.M., Dr. D. Paterson: Constipation and its Management.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.
THURSDAY, Jan. 21st.—5 P.M., Mr. J. B. Banister: Late Manifestations of Puerperal Sepsis.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn road, W.C.
*FRIDAY, Jan. 22nd.*—4 P.M., Mr. Armour Brown: Lateral Sinus Thrombosis.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.
FRIDAY, Jan. 22nd.—4.30 P.M. (at Whitworth-street West Branch), Dr. W. Fletcher Shaw: Urinary Symptoms in Women.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.
FRIDAY, Jan. 22nd.—3.30 P.M. (at the Royal Hospital), Dr. Skinner: Clinical Examination of Neurological Cases.

## Appointments.

INGRAM, J. T., M.D., B.S. Lond., has been appointed Pathologist to St. John's Hospital for Diseases of the Skin, Leicester-square.

SHERIDAN, MAY, M.B. Liverp., Assistant School Medical Officer for the County of Cheshire.

Certifying Surgeons under the Factory and Workshop Acts: PRESTON, J. A., M.D. Brux., L.R.C.P. Lond., M.R.C.S. (Oxted); JOLLY, G. A., M.B., Ch.B. Edin. (Orkney); and ARCHIBALD, A., M.B., Ch.B. Edin. (Renfrew).

Edinburgh Royal Maternity and Simpson Memorial Hospital: FERGUSON, J. H., M.B., C.M. Edin., F.R.C.P., F.R.C.S. Edin., and WATSON, B. P., M.D., F.R.C.S. Edin., Physicians.

# Vacancies.

*For further information refer to the advertisement columns.*

*Barnsley County Borough.*—Asst. M.O.H., &c. £600.
*Birmingham, Queen's Hospital.*—Hon. P.
*Bradford Children's Hospital.*—H.S. £100.
*Bradford Royal Infirmary.*—Two H.S.'s. Each £150.
*Bridge of Weir, near Glasgow, Consumption Sanatorium for Scotland Colony for Epileptics.*—Res. Lab. Worker.
*Burnley, Victoria Hospital.*—H.S. £180.
*City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.*—H.P. At rate of £100.
*Colombo Municipality, Ceylon.*—Jun. Asst. M.O.H. Rs.7200.
*Derby County Borough.*—Asst. M.O. £600.
*Dundee Royal Infirmary.*—Hon. Asst. Ophth. S.
*Edinburgh, Elsie Inglis Memorial Maternity Hospital, Spring Gardens, Edinburgh.*—Jun. Hon. Obstet. S.
*Edinburgh, Royal Infirmary.*—Two Asst. M.O.'s. £450 and £350 respectively.
*Elizabeth Garrett Anderson Hospital, Euston-road, N.W.*—Asst. Pathologist. £150
*Evelina Hospital for Children, Southwark, S.E.*—H.P. At rate of £120.
*Guy's Hospital.*—Phys. for Psychological Med.
*Hospital for Sick Children, Great Ormond-street, W.C.*—Res. Med. Supt. £300.
*Ilford Urban District Council.*—Chief Asst. M.O.H. £700.
*Leeds Public Dispensary.*—Sen. Res. M.O. £200.
*Lincoln County Hospital.*—Sen. H.S. At rate of £200.
*Liverpool, Royal Southern Hospital.*—Anæsthetist. £50.
*Manchester, Ancoats Hospital.*—H.P. At rate of £100.
*Manchester Committee on Cancer.*—Special Investigation Officer. £600.
*Metropolitan Hospital, Kingsland-road, E.*—Asst. P.
*Middlesex County Council Sanatorium, Harefield.*—Third Asst. Res. M.O. £400.
*Mount Vernon Hospital, Northwood, Middlesex.* — Hon. Anæsthetist.
*Oswestry, Shropshire Orthopædic Hospital.*—H.S. £200.
*Perth, James Murray's Royal Asylum.*—Asst. P. £300.
*Royal Chest Hospital, City-road, E.C.*— Cln. Assts.
*Shanghai Municipal Council, Public Health Dept.*—Asst. Health O. Tls.700 per mensem.
*Southport Convalescent Hospital and Sea-Bathing Infirmary.*—Res. Med. Supt. £600.
*Stafford, Staffordshire General Infirmary.*—H.S. At rate of £200.
*Sudan Medical Service.*—Four M.O.'s £E.720.
*Ventnor, Isle of Wight, Royal National Hospital for Consumption and Dis. of Chest.*—Jun. Res. M.O. At rate of £250.
*Windsor, King Edward VII. Hospital.*—Hon. Asst. Ophth. S.
*Wolverhampton and Staffordshire Hospital.*—H.S. At rate of £15.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments for Certifying Factory Surgeons: Nailsea, Somerset; Southend, Essex; and Yarmouth, Isle of Wight.

# Births, Marriages, and Deaths.

## BIRTHS.

BEWLEY.—On Jan. 9th, at Courtfield-road, Kensington, the wife of Dr. Bewley, of a daughter.

CHAPMAN.—On Jan. 6th, the wife of R. D. Chapman, L.D.S., of Welbeck-street, W., of a son.

KEARNEY.—On Jan. 4th, the wife of Dr. Kearney, Eppingdale, Leytonstone-road, Stratford, of a son.

MAITLAND.—On Jan. 8th, at Golders Green, the wife of Charles Titterton Maitland, M.D., M.R.C.P., of a daughter.

RAINER.—On Sunday, Jan. 3rd, at "Shirlands," Herne Hill, S.E. 24, Kathleen, the wife of Dr. Charles Farrell Rainer, —a son.

TAYLOR.—On Dec. 31st, 1925, at Cannes, the wife of Major D. M. Taylor, I.M.S., of a daughter.

## DEATHS.

ANDREW.—On Sept. 21st, 1925, at Rangoon, Charles Todd Andrew, B.Sc., M.B., Ch.B., Surgeon on s.s. Lancashire, aged 46.

ATKINS.—On Jan. 1st, at Handley, Salisbury, Francis Robert Lowth Atkins, M.R.C.S., L.R.C.P., of Burford, Oxon., aged 41.

BOWEN.—On Jan. 4th, at Swilly House, Plymouth, Fleet Surgeon A. G. W. Bowen, R.N. (retd.), aged 62.

DAVIES.—On Jan. 3rd, at Hurtmore Croft, Godalming, Francis Joseph Davies, F.R.C.S. (late of Abercarn, Mon.), aged 74.

GIFFARD.—On Jan. 5th, of heart failure, Major-General Sir Gerald Godfray Giffard, K.C.I.E., C.S.I., I.M.S. (retd.).

JONES.—On Dec. 22nd, 1925, at 19, Paget-street, Cardiff, David Rhys Jones, L.R.F.P.S., L.S.A., aged 80.

MACKENZIE.—On Jan. 7th, at Santa Margherita, Ligure, Dr. H. M. MacKenzie, aged 56.

ROBERTS.—On Jan. 8th, suddenly, at Claremont-hill, Shrewsbury, Alfred Dean Roberts, M.R.C.S., L.R.C.P., aged 58.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## LEGISLATIVE MEASURES FOR THE CONTROL OF ALCOHOL AND DRUG ADDICTS.[1]

BY F. S. D. HOGG, M.R.C.S. ENG.,
MEDICAL SUPERINTENDENT, DALRYMPLE HOME FOR INEBRIATES.

NEARLY all civilised countries have laws regulating or restricting liquor traffic and the sale of habit-forming drugs. With regard to alcohol some merely legislate for the issue of licences, for the hours of sale of liquor, and for the penalties incurred by breach of the conditions laid down. Others have adopted State or local prohibition.

In many countries, however, there are laws the object of which is by punishment, or other means, to restrain, control and attempt to cure, the chronic or periodic drunkard or the drug addict. These statutes may be classified as follows: (1) Penal measures regulating punishment by fine or short term of imprisonment. (2) Control in penal establishments for lengthened periods. (3) Interdiction—i.e., laws prohibiting the sale of liquor to drunkards. (4) Guardianship Acts regulating the appointment of curators or guardians endowed with legal power over the estate (or the person) of an inebriate, or both. (5) Control in institutions or homes, with a view to reformative treatment: (*a*) for the inebriate who makes voluntary application for admission; (*b*) for the inebriate who is a police-court recidivist, or who has committed offences caused or contributed to by drink or drugs; (*c*) for the inebriate who refuses control and manages to keep out of the reach of the law.

Penal measures range from small fines to terms of imprisonment for varying periods. In New South Wales, Natal, and Kenya the maximum penalty is six months; in the Cape of Good Hope and Massachusetts it is 12 months; whilst in Michigan and Germany it is two years—which is the extreme penalty that may be inflicted in this country for being in possession of habit-forming drugs. In Germany they have a utilitarian method of dealing with habitual drunkards, for "whoever gives himself up to drink to such an extent that he cannot support himself or those for whom he is bound to provide" is subject to the maximum term (two years) in the workhouse or in employment on works of public usefulness.

### *Interdiction.*

Interdiction appears to be regarded with favour in many parts of the world. The usual type of interdicting legislation provides that any person who by the excessive drinking of liquor mis-spends, wastes or lessens his estate, or greatly injures his health, or endangers or interrupts the peace and happiness of his family, may be proceeded against and prohibited from obtaining liquor. His name is given to the various vendors of drink, who are liable to punishment, as are any other persons who supply him with liquor. The period of interdiction varies. It may be for a fixed period, or it may depend, as in Queensland, upon the opinion of magistrates. Or, as in Manitoba and elsewhere, the interdicted may have to prove that he has been sober for a certain number of months. Whilst this method is, no doubt, of value in sparsely populated countries or in small communities, such as Guernsey, it is unworkable in thickly populated areas. The inebriate may be well known in the vicinity of his abode, but a short excursion into adjacent territory will generally relieve him of this incubus.

The Drunkards Act of 1911 of British Columbia carries interdiction a step further. Upon the written request of husband or wife, or any blood relation, a petition may be filed in the Supreme Court praying that an habitual drunkard may be interdicted. If the person be found to be an habitual drunkard, and unable to manage his affairs, he is treated as a minor and someone is appointed to manage his affairs. The interdicted one may regain his legal rights when he can prove that he has refrained from drunkenness for 12 months. The names of interdicted persons are open to public inspection, and any contract, bargain, sale, or business transacted with an interdicted individual is held to be void. This is a form of guardianship.

Sweden has a system peculiar to itself, which was made familiar in this country under the name of the Gothenburg System. The Bratt System, by which name the plan is now known, is a development on national lines of the system which was inaugurated in Gothenburg in 1860. The Bratt System received legislative sanction and support in 1917. Under this scheme the liquor traffic, both wholesale and retail, is under the control of companies who ration the individual consumer and exercise constant and strict supervision over the purchases of their clients, taking away the right to purchase from those who abuse that right. Ration or pass-books, which resemble cheque-books, are not issued to persons who are found guilty of drunkenness or certain crimes and misdemeanours. The rationing applies only to spirits and heavy wines, all persons being at liberty to purchase ad lib. the national light beers and wines—which are very light indeed when compared with those consumed in this country. It is claimed that the system has during the last ten years reduced the consumption of strong alcoholic drinks by 50 per cent., and had a proportionate effect in the reduction of sentences for drunkenness, while the alcohol addicts admitted to the central hospital for habitual drunkards fell from 581 in 1913 to 211 in 1923.

---

[1] Being an abstract of a paper read to the Society for the Study of Inebriety on Jan. 12th, 1926.

In some parts of Germany, Austria, Switzerland, Australia, Canada, and the United States, and in Tasmania, Jersey, and France, inebriates, in certain circumstances, can be placed, as if they were minors or insane, for their own benefit and for that of those dependent on them, under the care of a guardian, trustee, or curator. The power has the effect of deprivation of civil rights, of control and management of property, and in some cases of the inebriate's control over his own person. In some countries a guardian can be appointed when there is alcohol or drug excess only, in others when there have been more than three convictions of drunkenness during the year, or other offences accompanying alcoholism. In others it has to be demonstrated, in addition, that the person is a spendthrift, is wasting his estate, or is unfit to manage his affairs.

### *Control in Institutions or Homes.*

In many parts of the world there are statutes under which inebriates may place themselves voluntarily under control and treatment. In most instances the definition of an inebriate includes both alcohol and drug addicts. In Great Britain we have in addition to fines and short terms of imprisonment for drunkenness in public, or other offences, the power given to a court to inflict severe sentences of fines up to £200 and six months' imprisonment for a first offence, and £500 and two years' imprisonment for being a second time in illegal possession of certain habit-forming drugs.

The Dangerous Drugs Act has, so far as I am able to judge by the greatly reduced number of applications which I receive for the admission of drug cases, been productive of good. The few applications I have received during recent years have been nearly all from those who have daily access to such drugs—i.e., doctors, dentists, and chemists. It is for many addicts a prohibition law and allows the control of the person (in prison) who breaks the law. Interdiction (the "Black List") under the Licensing Act, 1902, is practically a dead letter. Our country is too crowded for this measure to be of real value. Under the Inebriates Acts, 1879–1900, we have control in retreats for the inebriate who makes voluntary application for admission. Any person desirous of admission to an inebriate retreat is required by this Act to sign a request for reception in schedule form before a justice of the peace. Such request must be for a definite period, not exceeding two years, to be named in the application. Two relatives or friends, of either sex, of the applicant must also sign a statutory declaration before a justice or a commissioner for oaths, to the effect that the applicant for admission is an inebriate within the meaning of the Acts. The definition runs as follows: "An 'habitual drunkard' is defined in the Act of 1879 as meaning a person who is, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself or others, or incapable of managing himself or herself, and his or her affairs. It will be noted that there is no reference to drug addiction, but a note was issued from the Home Office to the effect that 'intoxicating liquor' may include liquors other than alcohol, if their habitual intemperate use brings the consumer into the condition of an 'habitual drunkard.'" The intending patient must then voluntarily enter the retreat premises, where he may be detained until the expiration of the period for which he has signed. Should he escape at any time during the period of legal detention, a warrant may be issued for his apprehension and remission to the retreat. But he may be discharged before the completion of the period for which he has signed if such a course is considered advisable for various reasons; for instance, because further treatment is unnecessary, for urgent private affairs, or for ill-health. Or he may be allowed to leave the retreat on leave of absence and to complete—so long as he abstains from intoxicants—his period at home or elsewhere. I frequently advise intending applicants for admission to sign for the maximum period (two years) in order that they may have a long period of some control on leave of absence.

The alcohol or drug addict will often bargain that he is to be a free agent and arbiter of the duration of his treatment. Undoubtedly in some cases it is better to let him be a free party to his reformation, for ultimately it must rest with him to continue to abstain and to fight any inclination or temptation to relapse; but in other cases this liberty of action is inadvisable. Patients may be anxious to get back to ordinary life; or they may feel so fit after a brief treatment that they feel fully able to face the world and its temptations. Their treatment is cut short, and too frequently disaster follows. It is in guarding against some of these types that voluntary control under the Act is helpful. It is also advantageous for the relative or friend of the addict, who puts up money for his treatment.

In addition to voluntary control there exists under the Act power to control in State inebriate reformatories or certified inebriate reformatories those inebriates who commit certain offences against the law. At the present time, however, partly owing to economical reasons and because reformatories are filled up with border-land cases and mental deficients and other hopelessly incurable persons, and partly owing to the doubtful wording of the Act and the misinterpretation of its provisions by magistrates, there are no such institutions to which law-breaking inebriates can be sent. We have no guardianship laws for inebriates, nor have we any compulsory control of addicts who do not get "run-in" frequently or do not break laws.

### *Control in Great Britain.*

For the benefit of those who refuse treatment enforced control is the only practical remedy. And in those cases where immediate action is desirable, it should be possible to obtain an urgency order of detention.

Sir William Willcox pointed out in 1923 that special institutions and staffs would be required for the treatment of large numbers of cases; that these do not exist in this country, and that provision for them would be necessary before any legal enforcement for compulsory treatment were enacted. Doubtless the Government would not pass a measure of the sort if it could not see its way to providing the required institutions, but there would not be the same objection to the addition of a clause to the Inebriates Act, allowing the appointment of a guardian to control the person and estates of inebriates who are wasting their possessions and exposing their families to future destitution.

There was presented to the House of Commons in 1913, by Mr. Ellis Griffith, a well-considered Bill to repeal and replace the present Inebriates Act. This contained clauses (a) to allow a person to enter into an undertaking to abstain from intoxicants for a period not less than one year; or (b) to submit himself and the control of his person, for a period not exceeding one year, to the guardianship of a guardian who could prescribe a place of residence and who could prevent him obtaining intoxicants. A failure in the former case involved liability to committal to a retreat; in the latter it involved the appointment of a judicial guardian; or (c) to apply for admission to a retreat. (d) To allow the judicial authority power in certain circumstances to grant a compulsory order of committal to a retreat at request of guardian, relative, or friend. (e) To allow a compulsory order for the appointment of a judicial guardian and of maintenance out of the estate of the inebriate, of dependent persons. These proceedings could be held in private.

The Bill also contained provisions as to inebriates guilty of offences and the definition of "inebriate" included drug addicts. This Bill was, unfortunately, shelved owing to the outbreak of war. The clauses I have referred to were recommendations contained in the Report of a Departmental Committee appointed in 1898 to inquire into the operation of the law relating to inebriates and their detention in reformatories and retreats. An article on this report appeared in THE LANCET of Jan. 30th, 1909.

I think that nearly all, if not all, who have been brought into intimate contact with inebriates are far from content with the measures we possess in this country for dealing with them. Great Britain lags behind her colonies and other countries in not legislating for the control of the non-criminal addict, and therefore in not giving relief to unfortunate wives, husbands, children, and other relations.

I wish to acknowledge my great indebtedness to Dr. R. Welsh Branthwaite, H.M. Inspector under the Inebriates Act, for information and assistance, and also to numerous gentlemen in all parts of the world who have courteously responded to my requests for information.

---

## WEBSTER'S ROYAL RED BOOK.

THE new (267th) edition of Webster's Royal Red Book (London: A. Webster and Co., pp. 736, 7s. 6d.) has reached us. The statement on the front page that the work is corrected up to the latest moment before going to press is confirmed by internal evidence. The main content of this useful volume is an alphabetical list and a street list of the "nobility and gentry" occupying houses in London. Business firms, clubs, societies, and institutions are included, also lists of the personnel of Government offices and of the Houses of Parliament. Theatre plans conclude a handy and serviceable book.

## THE CONTROL OF TINEA CRURIS IN SCHOOLS.

IN 1922 Dr. Norman Hallows contributed an article to our columns[1] on the Control of Tinea Cruris (eczema marginatum, tinea marginatum, or dhobie itch). Correspondence followed, in which the late Dr. Clement Dukes[2] (Rugby) described how he had been led to try chrysarobin treatment, and later we published an article by Dr. Arthur Whitfield[3] on the Treatment of Ringworm in which tinea cruris was considered. In 1925 the Headmasters' Conference invited representatives of the Medical Officers of Schools Association to suggest measures for dealing with this widespread nuisance of schools, and Dr. L. R. Lempriere (Haileybury), Dr. Norman Hallows (Marlborough), and Dr. A. I. Simey (Rugby) were appointed to draw up recommendations. We publish the substance of these recommendations below.

Tinea cruris is probably spread by dust and by infected towels and garments. It is certainly much more prevalent in the community at large than is generally supposed, and although it chiefly affects the groins, armpits, and toes, it may, if neglected, appear elsewhere on the body.

To prevent fresh cases being imported at the beginning of the term the medical officer should have permission at his discretion to examine all boys in the senior houses when the term opens, and at such other times as circumstances warrant. The coöperation of boys and parents should be sought, and boys should be instructed to report redness and/or irritation of the thigh. Neglect to do so should be regarded as a serious offence against the community. Changing-rooms, drying-rooms, and lavatories should be adequate for their purpose, and every care should be exercised to ensure cleanliness and tidiness after use. Laundry arrangements of the school must be entirely satisfactory from a hygienic point of view. The danger of infection would be greatly decreased if (1) pants were worn with cloth clothes throughout the year, and if (2) where serge shorts are used, bathing drawers were worn underneath them. O.T.C. uniforms should be disinfected whenever their ownership is changed. Studies should be kept tidy and overcrowding avoided, and curtains, hangings, and draperies should be discouraged. Boots, flannels, uniform, and toilet articles should not be kept in studies, and any floor coverings used in dormitories ought to be removed and washed periodically.

A period of isolation accompanied by adequate disinfection is an essential part of treatment in every case, and in order that this may be as short as possible, the treatment hereafter described should be followed.

The leaflet accompanying these recommendations is to this effect:—

1. The naked-eye appearance of tinea cruris is usually so characteristic that a diagnosis can be made without microscopic examination. The fungus is not always easy to detect even in obvious cases of the disease, but experience shows that the very large majority of rashes in the groin area in schoolboys are due to infection by it. The whole surface of the body, especially the axillæ and internatal cleft, should be carefully examined to determine the extent of the disease at the outset.

2. The case should be isolated at once and kept in bed during sanatorium or bedroom treatment.

3. For at least six days apply thickly-spread dressings of either ung. chrysarobini B.P. or ung. ararobæ B.P.C. once daily and retain them in position by means of bandages or bathing-drawers, or else use liberal inunctions of the same twice daily. Where only one thigh is found to be infected both must be treated. It is essential to use a reliable and active sample of the ointment; that supplied by the General Apothecaries Co. has been found uniformly good.

4. During the period of treatment in bed the patient should be examined daily.

5. At the end of this period, provided that the applications have been adequate, it will be found that the central infected area has become smooth and pale with a surrounding red line and erythematous band at the junction of the infected and normal skin.

6. When a satisfactory result has been obtained the patient should have a hot bath and wash the affected area thoroughly with soap. (Baths are not advised during the period of treatment.) Clean disinfected clothing is then put on and the patient may then be discharged as free from infection.

7. As an additional precaution after discharge ung. ac. benzoici co. B.P.C. should be applied daily to the affected parts for from two to three weeks.

8. It is advisable that boys, after the course of chrysarobin treatment, should be inspected at weekly intervals and should report to the medical officer on return to school.

9. Disinfection is an essential part of the treatment, and should this be inadequate reinfection is almost certain to occur. Towels and all articles of clothing and bedding which may have come in contact with the infection should be either boiled or treated in a steam disinfector.

10. Desquamation between the toes should be carefully treated whenever it exists, either with the ointments above mentioned or by painting with tinct. iodi fort.

## RECURRENT PIN-HEAD PUSTULATION.

*To the Editor of* THE LANCET.

SIR,—I shall be grateful for the advice of your readers on the treatment of the following case. Recurrent pin-head pustulation of the chin in a man aged 51. The condition has been troublesome for more than 30 years. There appears to be nothing relevant in family or personal history. Patient has had slight acid dyspepsia from childhood. The skin on the chin is the only part of skin affected—that over other areas is quite clear and normal. There is no seborrhœa of scalp; teeth and mouth healthy; skin fairly free from comedones. The small pustules arise very quickly, sometimes 8 to 12 or more appearing in a morning when there was none the previous day, but only very small foregoing papules. Varied treatment has been tried from time to time, but none has been successful—e.g., externally: sulphur, ã salicyl., preparations of mercury—all these in forms of lotion and ointments; lot. calamin co., ung. resorcin, iodex, lot. calc. sulph., pulv. ã boric c ã salicyl., 5 per cent.; internally: iron, arsen., sulphur, synthetic preps. of garlic, alkalies, aperients.

I am, Sir, yours faithfully,

West Africa, Dec. 7th, 1925. ACNE.

## MATERNITY AND CHILD WELFARE PROBLEMS.

A REPORT[1] has just appeared of the lectures and round-table talks at the Baby Week Summer School held last July. The two main subjects discussed were the Formation of Character and Maternal Mortality and Morbidity in Childbirth, and in both sections the council was happy in having experts for speakers. Under the first heading various phases of psychology were dealt with, the lecturers including Prof. William Brown, Dr. J. A. Hadfield, Dr. Eric Pritchard, Dr. M. D. Eder, and Dr. A. F. Tredgold, whose paper on the abnormal child was a particularly valuable contribution, dealing clearly and concisely with abnormality in regard to (1) instincts, (2) feelings, (3) intellect, (4) intelligence. One or two striking definitions were given, as when Dr. Hadfield said, "By temperament we mean the influence of the *bodily* condition upon the mind," or Prof. Brown, "Disease in general, whether physical or mental, is disorder which, originally functional, may become so pronounced as to cause structural change, which may be established in the course of successive generations." In the discussion on maternal mortality, it may be noted that medical men and women of such varied experience as Sir Arthur Newsholme, Dame Janet Campbell, Dr. A. E. Giles, Dr. Mabel Brodie, Dr. R. A. Lyster, Prof. E. W. Hope, and Dr. H. K. Waller, without exception spoke in favour of maternity homes or some sort of institutional facilities for childbirth. Dr. Brodie wished especially to see more provision for complicated cases during pregnancy, and Dame Janet Campbell spoke of the desire of the Ministry of Health that cases of puerperal fever should be cared for in a small number of institutions where they would have the advice of skilled obstetricians. This has since been carried into effect in London by the setting apart of quarters in three of the Metropolitan Asylums Board Hospitals for the purpose. The general standard of the papers read at the school was high, and the National Baby Week Council has rendered a useful service in publishing them in cheap and compact form.

*Bacid Morgenstern.*—Messrs. E. H. Spicer and Co. inform us that this preparation (noticed in THE LANCET of Jan. 2nd, p. 24) is in future to be known as "B. Acidophilus Emulsion (Morgenstern)," under which name it has been admitted to the American "List of New and Non-Official Remedies."

*Longevity and Fertility.*—Mr. Robert Barr, of Magill, a suburb of Adelaide, who has recently celebrated his ninety-third birthday, went to South Australia in 1874 with his wife and ten children, nine of whom are still living. He is enjoying good health and has at present 68 grandchildren and 141 great-grandchildren.

# An Address

ON THE

# MAJOR PROBLEM OF PUERPERAL SEPSIS.

*Delivered on Dec. 10th, 1925, before the Windsor and District Medical Society*

BY VICTOR BONNEY, M.S., M.D., B.Sc. LOND., F.R C S. ENG.,

ASSISTANT GYNÆCOLOGICAL SURGEON TO MIDDLESEX HOSPITAL, SURGEON TO CHELSEA HOSPITAL FOR WOMEN, ETC.

THE subject of the prevention of puerperal sepsis is of constant interest because, sooner or later, the majority of medical men come face to face with the disease At intervals this interest is exacerbated by the written or spoken pronouncements of some obstetrical authority, and a series of letters appear in one of the medical journals written by correspondents mostly holding different views. Meantime the disease remains with us, not greatly diminished in frequency for the last 50 years in spite of a great deal of not entirely unacrimonious discussion. This is the outstanding fact, the failure to explain which keeps professional interest in the subject always simmering.

We know that puerperal sepsis is due to infection of the placental site and that the organism most frequently found is a streptococcus belonging to the hæmolytic group and most often identical with *S. pyogenes*. The question is, how did it get there?

### EXTRINSIC INFECTION.

The conveyance of organisms from individual to individual is the most easily understood method of producing sepsis, and as such was naturally the first to be discovered. As regards puerperal fever, Charles White, of Manchester, first of all, and Semmelweiss after him, recognised that the epidemics that ravaged lying in hospitals were due to infection of the recently delivered woman from an outside source, although they were ignorant of the exact nature of the infection. The discoveries of Lister made clear that the infection was organismal, but the idea that the source of the infection was invariably an extrinsic one was maintained for many years after, and is only to-day being superseded by a wider view. There is no wonder in this, for Lister himself at first regarded wound infection as being almost entirely of extrinsic origin and chiefly air-borne. Increasing knowledge showed that in certain kinds of wound infection the organisms did not originate from without but were resident in the individual before the receipt of the wound. This was recognised in general surgical practice much sooner than in obstetric work, because the surgeon is frequently called upon to operate on tissues or surfaces obviously infected or even inflamed before he makes his wound, whereas the obstetrician works through a canal which, together with its approaches, usually appears healthy although it may in reality be gravely infected. So soon as surgeons began to frequently operate on the intestine, the throat, the nose, or other heavily infected surfaces, it became clear that the original antiseptic technique of Lister, which had for its object the prevention of extrinsic infection, was inadequate to prevent the wounds going wrong, since they became infected from the organisms already present in the part. Surgical technique has, therefore, been modified to meet this second source of infection as well, but the problem it presents is far more difficult of solution than that presented by the earlier recognised extrinsic infection, and, indeed, is only partly solved at the present day.

The maintenance of belief in extrinsic infection as the chief cause of puerperal sepsis is largely due to the dramatically rapid disappearance of the disease in its epidemic form, which at once followed the application of the Listerian principles to obstetrics. Such epidemics were certainly due to extrinsic infection, but that the patients so infected only formed a small proportion of the total number of cases of puerperal sepsis is obvious from the fact that, in spite of the abolition of epidemics, the yearly total of cases in the country has diminished relatively little in spite of the general employment of antiseptic measures—rubber gloves, for example—quite sufficient to make extrinsic infection extremely unlikely, if not to rule it out altogether. The finding of the specific cure of any disease or condition is immediately followed by unmistakable and striking results. The discovery of extrinsic organismal infection and the antiseptic measures for preventing it at once transformed surgery, because before Lister's day the majority of surgical cases "went wrong" because of extrinsic infection. Take, for instance, the operation of opening the knee-joint, which before Lister's time was almost uniformly fatal and now is performed with impunity Infection of surgical wounds still occurs, of course, though with much lessened frequency, because although extrinsic infection has been rendered very unlikely the safeguards against intrinsic infection still leave much to be desired, and there are certain operations (e g, on the bowel) in which this variety of infection is the chief danger. In obstetric work, on the other hand, no such striking transformation has occurred, for the reason that extrinsic infection, even in pre-Listerian days, was of far lesser frequency than intrinsic infection, and therefore an anti sepsis, primarily intended to guard against the former manner of infection, and against it alone, has relatively failed.

### INTRINSIC INFECTION.

Every human body harbours on or in it enough organisms of potential virulence to fatally infect a wound of that body, given that the initial organismal implantation be in sufficient numbers to overcome the resistance of the tissues in the area of implantation. In puerperal sepsis the attacking organism is usually a streptococcus, and the wound infected is the placental site, and as it is certain that the uterus before labour is, as a rule, sterile of organisms, the streptococci must, as a rule, infect the placental site during or after the labour. Bond showed that minute particles placed in the upper vagina found their way unassisted into the uterus and tubes, and this has been confirmed by Everard Williams and Russell Reynolds,[1] who also found that in animals at all events previous artificial closure of the abdominal ostia prevented the particles from ascending. He suggested that the agency of ascent was an aspirating action from the peritoneal cavity. It would appear almost certain, then, that during the early puerperium, when the uterine cavity is open to the vagina and so soon as the tubes have regained continuity with the uterine cavity,[2] organisms from the lower canal must frequently find their way upwards.

That streptococci are frequent inhabitants of the vagina in apparently normal pregnant women is not now in dispute. Lockhart,[3] whose very fine paper should be studied in this connexion, found them in 48 per cent. of the cases he investigated, and FitzGibbon and Bigger[4] in 68 per cent.

If this were all, the problem of puerperal infection would lie in explaining, not how infection of the placental site occurred, but why it occurred so seldom. It is, however, not all; research shows that the streptococci inhabiting the vagina before delivery are rarely hæmolytic, whilst those found in the uterus in puerperal sepsis most commonly are hæmolytic. Moreover, when hæmolytic streptococci are found in the vagina before labour they are very rarely of the variety *S. pyogenes*, which is the organism chiefly found in puerperal sepsis. That non-hæmolytic streptococci can occasion puerperal sepsis is, however, certain, for in a minor proportion of the cases they are the only organisms found in the uterus. Thus FitzGibbon and Bigger[4] found that, out of 47 septic cases from which they isolated streptococci, there were eight in which the organisms were non-hæmolytic, and of these four died. The capacity of non-hæmolytic streptococci to produce severe inflammation is, moreover, proved by the bacteriology of acute appendicitis. Dudgeon and Mitchiner,[5] from 27 cases isolated streptococci 19 times, and of these, in no less than 18 the organism was non-hæmolytic. The fact that, in puerperal sepsis, the bulk of the streptococci found are hæmolytic is regarded by some as proving the origin of the disease to be commonly extrinsic, but no such conclusion should be drawn, for it is to be remembered that as a differentiator between virulent (usually hæmolytic) and non-virulent (usually non-hæmolytic) streptococci the uterus is an infinitely more delicate selective culture medium than anything that has yet been produced in a laboratory. Given that of various streptococci gaining access to the placental site, only one in a thousand was virulent and hæmolytic, in 24 hours it would become the predominant organism, although in laboratory cultures taken before the septic proliferation had begun it would be undetectable, being overgrown by the much more numerous avirulent non-hæmolytic organisms. Lockhart's remarks in this connexion should be studied. Moreover, although the experimental transformation of non-hæmolytic into hæmolytic streptococci has only occasionally been successful in the laboratory, it is not certain that it does not occur in the septic puerperal uterus. On this matter Lockhart's observations are again very illuminating. Of 48 women from whose vaginæ streptococci were isolated before the labour, 18·7 per cent. developed pyrexia after the labour, although the organisms found before labour were hæmolytic in one case only; whilst of 52 women whose vaginæ did not contain streptococci before labour only 1·9 per cent. developed pyrexia after their labour. Hæmolytic streptococci were found in abundance in the vaginæ of four of the puerperal women from whom non-hæmolytics alone had been isolated before labour, their appearance coinciding with the onset of post-partum pyrexia. It can be argued that these had probably been introduced during or subsequent to the labour, but it is certainly possible that they derived from hæmolytics present in too small a number before labour to be detected, or were the result of the conversion of the non-hæmolytics then discovered.

---

[2] The question how soon after delivery communication between the tubes and the uterine cavity is effected after delivery needs answering if the ascent of particles from the vagina into the uterus is due to aspiration from the peritoneal cavity.

[3] Brit. Jour. of Obst. and Gyn., vol. xxxii., No. 1.

[4] Ibid., vol. xxxii., No. 2.

Given, then, that the causative organism is resident in the woman before labour, it will be manifest that there are two manners of infection of the placental site, "autogenous" intrinsic infection and "conveyed" intrinsic infection.

### Autogenous Intrinsic Infection.

Intrinsic infection can only be called "autogenous" when the septic organisms attain the placental site unaided by manipulation or instrumentation. There are two possible ways in which they may do this: (1) Organisms resident in the upper vagina may ascend into the uterus during or subsequent to the labour. (2) They may be transplanted there by the blood-stream before, during, or after labour.

*Spontaneous Organismal Ascent.*—(1) That organisms in certain number do ascend into the uterus during the puerperium seems undoubted. That they do not commonly produce sepsis can be explained by the facts that (*a*) they are usually of low virulence, (*b*) that blood (the lochia) possesses bactericidal powers, and (*c*) that the tissues of the placental site are more or less resistant. Autogenous organismal ascent is best of all demonstrated by the much increased likelihood of sepsis which accompanies Cæsarean section when it is performed after the membranes have ruptured and the uterine cavity is in free communication with the vagina, even in cases in which there has been no intra-vaginal manipulation beforehand and in which vigorous methods have been taken to sterilise the vagina before opening the uterus. It must be admitted that, when sepsis follows Cæsarean section, it does not, as a rule, exhibit the typical clinical features of virulent "puerperal fever," but this is not surprising firstly because the chances are against very virulent organisms being present in the vagina, so that the infection would be, as a rule, of relatively low intensity, and secondly because the surgeon's wound in the uterus, with its many foreign-body sutures, probably offers far less resistance to organismal invasion than the placental site. It is certain that, in the majority of cases of Cæsarean section gone septic, the symptoms suggest that the main area of infection is the uterine and abdominal wounds and not the placental site, though I have seen typical "puerperal fever" follow the operation.

There are individuals who are habitually infected with streptococci, the organisms residing either in their nasal sinuses, gums, tonsils, urinary tract, or intestine, or in several of these sites coincidently. Certain of these persons may be described as suffering from generalised streptococcosis, and in them the body resistance to this organism is probably abnormally low. Any injury is likely to go hard with such an individual, birth injury included.

Streptococcal vaginitis of non-venereal origin is a condition very commonly met with, not only in married women of all ages, but also in virgins. The source of the infection is probably intestinal in most cases, and from many of these patients streptococci can be recovered from the urine as well, whilst in others it is obviously only one manifestation of a generalised streptococcosis. It is a most intractable type of infection, and may continue for years in spite of vigorous treatment, a fact which suggests that reinfection is continually occurring, as it would do if the primary source was in the intestinal tract and this remained untreated. If a woman with streptococcal vaginitis becomes pregnant the probability is that the organisms will ascend into the uterus after the labour, where they may or may not produce symptoms according as the resisting power of the placental site be high or low. In this connexion I will quote a case which exemplifies the views I am putting forward. The patient was a young woman whom I was called in to see on account of puerperal fever which had followed in two days a normal and entirely uninterfered-with labour, the child and placenta having been born before the doctor arrived. It was her third child, and I was informed that both her first and her second labours had been followed by high fever and signs of sepsis. On examining her I noticed that, although her teeth were perfect, her gums were purple and pulpy and showing marked recession. This condition was a sequela of scarlet fever at the age of 13, which had persisted in spite of every treatment except the removal of her teeth, to which she had resolutely objected. The attack of puerperal sepsis on this occasion proved fatal, and there can be no reasonable doubt that hers was a case in which extensive harbourage of virulent streptococci had existed for years, with consequent chronic infection of her intestinal tract and probably of her vaginal and urinary passages as well.

*Blood Infection of the Placental Site.*—That wounded tissue may become infected through the blood-stream is undoubted, and therefore the possibility of such happening to the placental site cannot be denied, especially in the case of a woman suffering from generalised streptococcosis. It must be remembered that the carriage of organisms by the blood appears to be a much commoner occurrence than was formerly believed to be the case; witness pyelitis in which the causative organisms almost certainly enter the kidney through the blood-stream. Nothing definite is known about blood-borne infection of the placental site and the subject has received little attention, but its occurrence would explain these occasional cases of puerperal sepsis in which the symptoms date from the very onset, or even precede, a perfectly normal and uninterfered-with labour. In a woman the subject of generalised streptococcosis the uterine wall before labour may conceivably contain streptococci.

---

[4] Brit. Jour. of Surg., vol. xi.

*Conveyed Intrinsic Infection.*—Though intrinsic infection is undoubtedly at times autogenous, there are strong reasons for believing that, in the majority of cases, it is conveyed; that is to say, the septic organisms, though derived from the patient's own body, are transported into the upper vagina or the cavity of the uterus by the agency of hands or instruments. The source from which the organisms of conveyed intrinsic infection are most usually drawn is undoubtedly the bowel, whose organismal content is derived not merely from the stomach and intestine, but from the drainage of the nose, mouth, pharynx, and throat.

A consideration of the results which follow traumatic perforation of the gut or bruising or strangulation of its wall leaves one in no doubt that of the organisms present in the intestine many are potentially virulent, even in the most healthy person. Far from being easily tolerated by the tissues, they are, in fact, held within bounds by a fence of tissue resistance so delicate that the least injury to it is followed by an invasion more or less dangerous. Seeing the position of the vagina in relation to the rectum, the relative freedom from intestinal organisms of the former canal, when in perfect health and in the virgin state, is remarkable, though they are much more frequently found, especially towards its lower end, in the married and parous The approaches to the vagina —viz., the vulva and the perivulval and perianal skin—are always heavily infected with organisms derived from the bowel, and it is a bacteriological impossibility to pass anything into the vagina without carrying up some organisms from the outside. The character of the organismal infection thus effected will depend on the character of the bacterial content of the fæces, and this varies in different individuals. In the majority of persons *B. coli* is predominant, while streptococci are sparse and chiefly of the "fæcalis" group, but sometimes this proportion is reversed, *S. fæcalis* being abundant and *B. coli* sparse. In other persons again, *S viridans* or types allied to it are present in large numbers. This organism is of the type commonly found in the mouth. *S. pyogenes* is not commonly found in the bowel, but the technique for separating the various organisms present in a culture as mixed as the fæces is not yet perfect enough to always detect an organism present in small numbers. The fæcal organisms, as has been said, are derived not merely from the intestine but from the throat, nose, and mouth, and in infective states of these parts are passed down into the rectum. Pilot and Davis[6] and others have shown that hæmolytic streptococci are commonly present in the tonsil, while they are the organisms usually responsible for bronchitis and broncho-pneumonia. They are also present in pyorrhœa and in scarlet fever, though the variety in all these conditions differs in certain details from *S. pyogenes.* It is thus apparent that the infection of the vagina conveyed by the passage of something into it must be regarded in every case as potentially a virulent one.

The fact that *S pyogenes*, the commonest organism of severe puerperal fever, is apparently rarely present in cultures of the fæces has been held to prove that in the majority of the grave cases (those exhibiting *S. pyogenes*) the infection was not derived from this source. Closer consideration of the matter, however, shows that on the contrary the fact cited fits in very well with the view that they *are* so conveyed. For if *S. pyogenes* was constant in the fæces, then most women during their confinements would have it introduced into their vaginæ in the process of vaginal examination and severe puerperal sepsis should be very common indeed. That it occurs a great deal too often is admitted, but with nothing like the frequency postulated by the assumption. The proportion of deaths by puerperal sepsis in England and Wales at the present day may be taken at about 1 3 per 1000 live births, and it may be accepted as certain that the great proportion of those women die of streptococcal infection. The proportion of cases of hæmolytic infection (*S. pyogenes*) to those of non-hæmolytic infection (*S. viridans, S. fæcalis,* &c.) in severe puerperal fever may be taken in general as somewhere about 3 to 1, or 75 per cent (FitzGibbon and Bigger 70 per cent., Hauch 80 per cent.), and there is no reason to materially alter this estimate for the group of cases that die of the disease, for FitzGibbon's and Bigger's series show that the non-hæmolytic was at least as fatal as the hæmolytic infection. Thus we may roughly assume that one woman dies of *S. pyogenes* infection of her uterus for every 1000 labours. Now, the death-rate of cases of puerperal fever due to streptococcic infection (whether hæmolytic or non-hæmolytic) is roughly 40 per cent., that is to say, of every five women so affected two die and three recover,[7] and on this estimate there are five cases of puerperal fever due to *S. pyogenes* for every 2000 labours, or one for every 400 labours. If, then, we make the very modest assumption that the presence of *S. pyogenes* in the fæces would only be followed by infection of the uterus once in four times, then that organism would only be required to be present in the intestine of one parturient woman out of 100 such—i e , with a rarity which fits in with the bacteriological findings.

That the infection has an intestinal source in many cases is strongly suggested by the frequency with which *B. coli* accompanies streptococci in the infected uterus I and A. G. R. Foulerton, in our investigation into the causation of puerperal infections, published in 1905,[8] found this conjunction in 50 per cent. of all the cases from which we isolated streptococci from the uterus At that time we explained the presence of *B coli* as being due to a secondary infection, but subsequent consideration leads me to think that that view was probably wrong and that the colon bacillus gained entry to the uterus concurrently with the streptococcus.

### PREVENTION IN VIEW OF CAUSATION.

The problem of how to prevent puerperal fever fundamentally depends on a true appreciation of the sources and mechanism of the infection. These may now be summarised in the following table, a study of which at once suggests the formidable difficulties we are up against.

*Septic Infection of the Placental Site.*

| Source of infection. | | Manner of infection. |
|---|---|---|
| 1 *Extrinsic* Organisms alien to the woman introduced during or after labour. | | (1) Intra-uterine manipulation or instrumentation. |
| | | (2) Intravaginal manipulation or instrumentation, plus spontaneous organismal ascent from the vagina |
| 2 *Intrinsic* Organisms resident in or on the woman at the time of labour | A. | (1) Blood infection. |
| | | (2) Spontaneous organismal ascent from the vagina |
| | C. | (1) Intra uterine manipulation or instrumentation. |
| | | (2) Intravaginal manipulation or instrumentation, plus spontaneous organismal ascent from the vagina. |

A = Autogenous. C = Conveyed

*Prevention of Extrinsic Infection.*—Considering first infection from an extrinsic source because the problem of its prevention is comparatively simple, we may, at the outset, rule out air infection, since it has been shown that aerial transport of septic organisms practically does not occur—a mercy indeed, for if dust was an active agency surgery would be impossible. There remain, then, the persons, instruments, and appliances of the attendants. Instruments and appliances can with certainty be rendered sterile, and, in fact, are so in practically every case nowadays. The hands of the attendants can also be rendered safe by wearing sterile rubber gloves, and this again is common practice. That instruments, ap- and gloves initially sterile can act as convey infection into the vagina or uterus is, however, obvious, if subsequent to sterilisation they are brought in contact with an infected surface, but as regards infection from an extrinsic source, this could only happen as the result of great carelessness and one may add extraordinary ill luck, for the surfaces of the towels, sheets, tables, basins, and so forth, in an ordinary lying-in room, though not sterile, probably not once in many thousand times are contaminated with virulent streptococci.

---

[6] Amer Jour of Infective Diseases, April, 1919.

[7] The writer and A. G R. Foulerton had 10 deaths FitzGibbon and Bigger 20 in 47

[8] Trans Obst Soc. of London, vol. xlvii

There is, however, another source of extrinsic infection more difficult to shut out—namely, the throat, nose, and mouth of the attendant. That these regions are frequently the seat of potentially virulent streptococcic infection is undoubted. That such might be conveyed by the salivary spray of persons suffering from tonsillitis, sinusitis, or gingivitis must be admitted. This is recognised in surgical work, where no operation is performed without the operator and his assistants being masked. Obstetric operations differ in no essential from those of ordinary surgery, and logically the same precautions should be observed. Infection by salivary spray has been held by certain writers to be a ready explanation of the occurrence of puerperal sepsis. Whilst agreeing that it probably sometimes occurs, I am of opinion that it does so rarely, for having had a long experience both of the "pre-mask" and "mask" periods of surgery, I know that mask wearing has not made that difference to surgical results which it should have done if infection by salivary spray was at all common.

When, then, we review the possibilities of extrinsic infection, and the means that have been taken, and are taken to-day, against it, and consider the relatively poor results achieved, we have, I submit, no option but to believe that beyond this source of puerperal sepsis there is another which operates with much greater frequency, to the prevention of which I shall now turn.

*Prevention of Intrinsic Infection.*—Given that organisms potential for puerperal sepsis are already resident in or on a woman before labour, our countermoves against the menace to the placental site are clearly as follows: 1. To prevent or do away with all foci of septic harbourage before the labour, or if possible before the pregnancy. 2. If this is impossible, to take measures to prevent living septic organisms reaching the vagina. 3. And if this is impossible because the vagina is already infected, to take measures to prevent living septic organisms reaching the uterus; or if the uterus is already infected or has, of necessity, to be infected during the labour, to take steps immediately the labour is over to destroy the organisms present in the uterus. 4. To raise the resistance of the body tissues against all infection from wheresoever menaced.

The general plan of campaign, then, is simple, but it needs scarcely a moment's thought to realise that its accomplishment is confronted by many difficulties.

### Abolition of Septic Foci.

The final logical outcome of our argument is obviously that a woman should not conceive until it is certain she harbours no potential sepsis. This is a counsel of perfection which, in its fullest sense, will probably never be attained; for to begin with, no hard-and-fast line can be drawn as to what constitutes menaced sepsis; for instance, most of the organisms normally present in the intestine are potentially virulent. On the other hand, much can be done in this direction that has hitherto not been done or done imperfectly. The prevention or cure of such things as chronic tonsillitis, sinusitis, or gingivitis has a special desirability in the case of a woman likely to become, or presently to become, a mother, as have also attention to the teeth, general hygiene, and cleanliness. Conception obviously carries an increased risk in a woman suffering from vaginitis, and as far as a medical man may influence such a matter he should advise against pregnancy until the vaginitis is cured. A vaginitis complicated by pregnancy should be treated vigorously, though it must be owned that the difficulty of doing this successfully is great. Though at first it may appear fantastic, remorseless logic leads to the conclusion that the bacterial content of every pregnant woman's vagina should be ascertained from time to time, so that the obstetrician may take what precautions are possible in the event of organisms likely to produce sepsis being found there. The urine also should be examined for bacteria. And, still pursuing the logical sequence, it is plain that the bacterial content of the intestine should be investigated. Here we are at once up against the difficulty that the bacteria most plentiful in the fæces are, even in the most healthy person, potentially pathogenic. That there is considerable variation in the bacterial content of the intestine I have already pointed out, and, other things being equal, it would appear that the woman in whose fæces streptococci predominate stands in greater risk of puerperal sepsis than the one in whose fæces the colon bacillus is in major quantity. We are, however, only at the beginning of understanding as regards these matters, and our laboratory methods for separating, classifying, and estimating the pathogenic possibilities and probabilities of the intestinal bacteria leave much to be desired. I visualise, however, a time when our knowledge will be so much more precise that the bacteriologist will be able to warn the obstetrician that this or that particular patient carries in her intestine organisms which menace in an abnormal degree the safety of her delivery.

### Safeguarding of the Vagina.

The abolition of all septic harbourage, especially in the near neighbourhood and the approaches of the vagina, is at present impossible, and hence the next obvious item in our campaign against puerperal sepsis is to prevent septic organisms reaching the vagina. This is impossible in those cases in which the vagina already contains streptococci, but these are in the minority, for the bacterial content of that canal, when perfectly normal, is an innocuous one. I have already pointed out that it is a practical impossibility to pass anything into the vagina without transplanting into it some of the organisms resident on its approaches, and these approaches are always more or less fouled by intestinal bacteria and sometimes by organisms derived from the urine. Nothing, therefore, should be passed into the vagina that can be avoided, not only during labour but for some time beforehand. Blair Bell has published evidence which suggests that coitus during the last few weeks of pregnancy may convey into the vagina organisms which, later, produce puerperal sepsis. In view of what we know, this seems quite possible, especially if the male organ is in an infective state from balanitis, cowperitis, urethritis, or prostatitis, but beyond this intestinal organisms are certain to be carried up in the act and some of these may be actively pathogenic.

The fingers and instruments of the obstetrician are a still more likely agent of conveyed intrinsic infection. Gloves can be worn and instruments boiled, but as conveyers of organisms from the vaginal approaches they are just as efficient as the bare hand and the forceps taken out of the hip pocket. Once again we are up against a difficulty, for fingers and instruments must be used in obstetric surgery. In certain regions of the body, as for instance the abdomen, the surgeon can guard against the conveyance of organisms from the skin by covering the edges of his wound with towels or sheet rubber, but the vaginal orifice through which the obstetric surgeon has to work does not lend itself to this. We can, however, endeavour to sterilise the perianal and perivulval skin by the application of a strong, non-irritating antiseptic, and this being done sterile towels should be affixed so as to cut out of the operative field the most infected part of the danger area—i.e., the anus and perianal skin. Even with such precautions the risk of conveyance is not entirely done away with, for organisms may lie inside our protective barrage. This possibility can be coped with by anointing the finger, hand, or instrument with some powerful but non-irritant antiseptic before it is passed into the vagina, so that if any organisms are carried up in the process they get a lethal dose in transit. For this purpose I use "violet green," the antiseptic introduced by Carl Browning and myself some ten years ago.

### Safeguarding the Uterus.

But there are cases in which the vagina is already infected with streptococci by the time labour begins, and these women stand in peculiar jeopardy from spontaneous organismal ascent during the puerperium and from direct manual or instrumental conveyance of the organisms into the uterus during the labour. When a woman is known to be suffering from vaginitis, the practitioner will be on the alert against these dangers, but unfortunately the presence of virulent organisms is not always announced by visible signs of inflammation. It is safest, therefore, to regard every vagina in labour as though it was septic and to avoid as far as possible the passage of anything through it into the uterus. If such passage has to be made, then the vagina should be thoroughly swabbed out beforehand with a strong non-irritant antiseptic, and the hand or instrument, before it is passed up, should be anointed with the same. Where infection of the placental site is specially to be feared, as, for instance, when the patient has an obvious vaginitis, the further precaution should be taken of either swabbing out or douching out the uterine cavity at the conclusion of the intra-uterine manœuvres. I need scarcely remind you in this connexion that manual removal of the placenta or any intra-uterine manipulation after the placenta is delivered is far more dangerous than turning the child or rotating the head within the amniotic sac, since the membranes protect the uterine wall from infection. It might be thought that during the puerperium spontaneous organismal ascent could be prevented, or at all events rendered harmless, by antiseptics applied to the vagina, and so it could be if we had a sufficiently powerful yet innocuous antiseptic at our disposal, and means of easily introducing it into the vagina so that the whole surface of the canal was flooded with it. In practice, however, this is well-nigh impossible, and the attempt carries with it the risk of conveying organisms from the vulva and its approaches. Douching in the puerperium has, therefore, been largely given up of recent years, though there are occasions on which it is the right thing to do if it can be done thoroughly.

There are certain cases of profound vaginal infection in which the best course is to discard that passage as the route of childbirth and perform Cæsarean section before labour has begun. This avoids the possibility of the obstetrician having to directly infect the uterine cavity in the course of intra-uterine manipulations forced on him by the exigencies of the labour, but it does not, of course, entirely abrogate spontaneous organismal ascent during the puerperium. As an example, where the choice lies between Cæsarean section and induction of labour, and the vagina is known to be infected, the abdominal operation is the one to be chosen. Finally, there remain those very grave cases in which the uterus is apparently infected before labour and fever is present from its start or even before it starts. I believe that in some of these the best chance would be given the woman by performing hysterectomy directly the child was delivered.

### Raising Resistance.

Finally, as it is certain that our best endeavours to hunt out and kill the organism, or even to prevent it reaching the uterus, are, in the present state of our knowledge, liable to fail, the question of whether it is possible to raise a pregnant woman's resistance to streptococcal infection merits very serious thought and research. It is no new idea, as you know, and vaccines and serums have been tried quite extensively but up to now with no definite results. That it should be possible to do it with certainty seems reasonable, and that it will be possible in the future I have no doubt. Even as matters stand to-day I think you will agree with me that in a case where streptococcal infection is specially to be feared, prophylactic doses of antistreptococcic serum should be administered.

### Necessity for Improved Conditions.

The scheme of prevention that I have outlined makes great demands on the medical man, and it is impossible for him to comply with them unless he is granted the requisite means, material, and environment. I have before protested against the inadequate circumstances under which much midwifery in this country is carried out and will not repeat myself beyond reiterating my conviction that no great diminution of puerperal morbidity and mortality can be expected until the public is prepared to pay for the things that are necessary for safety in childbirth.

I have ventured to liken the measures required to abolish puerperal sepsis to the moves of a campaign, and, I would add, a very arduous one at that, because the enemy we contend against is rarely in the open but wages a guerrilla warfare by ambush from unexpected quarters. The struggle has been going on indeterminately for more than 50 years, and as far as I can see will so continue until the man in the front line, the doctor in charge, can fight on a more advantageous *terrain*, with more reliable weapons and methods to his hand and better and more readily available help behind the line.

---

## THE TREATMENT OF
# ACUTE BACTERIAL INFECTIONS
## WITH INTRAVENOUS INJECTIONS OF PERCHLORIDE OF MERCURY AND MERCUROCHROME.

By LEONARD S. DUDGEON, C.M.G., C.B.E.,
F.R.C.P. Lond.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LONDON; DIRECTOR OF PATHOLOGY, ST. THOMAS'S HOSPITAL.

The treatment of acute bacterial infections by intravenous injections of perchloride of mercury and mercurochrome 220 is recorded in this communication. The fact that we are without specific treatment for many of the acute bacterial infections has resulted in the trial of various chemical preparations of recent years. I have devoted considerable time to many of these preparations and, therefore, it appeared to me that some advantage might occur if my observations with perchloride of mercury and mercurochrome 220 were put on record. Experience has led me to recognise very fully the necessity to commence such treatment at the earliest possible period from the onset of the illness, just as is now generally recognised to be the essential feature in the treatment of diphtheria and tetanus with the appropriate antisera. In my opinion valuable time is frequently lost in the desire to prove that an infection is generalised as judged by the cultivation of bacteria from the blood. This is especially the case with septic infections complicating obstetrical operations and those due to *S. aureus.*

The *Staphylococcus aureus* by no means infrequently produces an acute inflammatory process of the skin and subcutaneous tissues which may resemble an anthrax pustule. The intensity of the local lesion may not be sufficiently realised, but a fulminating general toxæmia may develop so that death occurs in a few days from the onset of the illness. It is remarkable how rapidly some of these acute bacterial infections advance, as if the patient's resistance were entirely in abeyance, and it is still more serious when we consider that these patients were more often young adults and apparently in perfect health before the illness commenced. It is difficult to believe that satisfactory treatment will be evolved to combat these acute septic infections unless such treatment is carried out at the earliest possible moment. I have treated 330 cases of acute bacterial infections with perchloride of mercury or mercurochrome 220 soluble, or with both these preparations, and in the vast majority of cases the actual treatment has been carried out in detail by me.

Personal experience at the outset in the intravenous administration of therapeutic preparations is desirable. Unfortunately in 25 instances out of these 330 cases the patients were moribund when I was asked to commence treatment, and nothing short of a miracle was likely to have been of the slightest effect towards favouring the patients' chances of recovery. In most of these cases no active treatment had been employed during the acute and brief illness, but in some of the streptococcal infections small doses of antistreptococcal sera had been administered. In all 47 deaths occurred, including six cases of malignant endocarditis, which entirely failed to respond to treatment with either or both of these preparations. This is not surprising when we consider the pathological changes found at autopsy in malignant endocarditis, and that in my experience the disease is usually far advanced by the time the diagnosis is arrived at.

It is a legitimate argument to adopt that some of the patients treated by the intravenous inoculation of perchloride of mercury or mercurochrome 220 soluble, would have recovered without this line of treatment, but this question cannot be definitely settled, although there is very little doubt that it is correct. In the early periods of these acute infective processes it is not possible to form an accurate judgment of the chances of a patient's recovery, and we have no information to guide us as to the length of time which is safe for the infection to remain untreated. It is desirable, therefore, to commence treatment in the early stages of the illness, even if a certain proportion of patients are inoculated with perchloride, mercurochrome 220, or other remedy who might have recovered otherwise.

### *Perchloride of Mercury.*

The first case of septicæmia which I treated with perchloride of mercury occurred in 1918 in the Balkans.

The patient, a soldier, was suffering from an acute illness which was diagnosed on clinical evidence as malignant malaria. There were no physical signs except enlargement of the spleen and pyrexia, but, as he had been for two years in the Balkans, the infection was regarded as malarial in origin. This acute illness, however, was unaffected by quinine. A complete bacteriological examination of the blood and urine was made when the patient's temperature was 105° F. I then gave him 1/16 grain (gr.) of perchloride of mercury in 10 c.cm. of normal saline, intravenously, which was repeated about 12 hours later as no improvement had occurred. After the second injection the temperature fell rapidly from 105° to 100° and then to normal, and the patient made a complete and rapid recovery. The only ill effects were a sharp attack of diarrhœa and mercurial stomatitis, both of which responded to treatment. No malarial parasites were found, but a hæmolytic streptococcus was cultivated from the blood.

It was not until after the war that I employed this method of treating acute bacterial infections on a relatively large scale. The dose given to the patient referred to above was considered at the time to be the maximum advisable and was dissolved in 10 c.cm. of saline, so as to reduce the possibility of local thrombosis to a minimum, but the various essential points at present adopted in this method of treatment will be referred to subsequently.

I have now treated 200 cases of acute bacterial infections with perchloride of mercury; these cases, which were in no sense selected, included puerperal fever, *Staphylococcus aureus* infections (including severe cases of boils and carbuncles), infections due to hæmolytic and non-hæmolytic streptococci, *Bacillus coli* infections, and other septic processes. Twenty-seven cases of puerperal fever were treated and 22 recovered. From three of the cases which recovered hæmolytic streptococci were cultivated from the blood, from two cases non-hæmolytic streptococci. From the remainder blood cultures were sterile or were not made, but from all the fatal cases streptococci were isolated from the blood. Hæmolytic streptococci were obtained from the region of the cervix in every case.

Baccelli[1] many years ago employed intravenous injections of mercuric chloride for the treatment of syphilis, and in 1907 he recommended this treatment for gonorrhœal rheumatism. There is very little reference in the literature to the perchloride treatment of acute bacterial infections, but in 1918 it appears to have been used in various parts of the world. Vecki,[2] of San Francisco, employed a solution of 1 in 1000 for intravenous injections and gave 3·5 c.cm. (which is nearly one-sixteenth of a grain) and repeated the dose when necessary, while in chronic cases he repeated the injections on several occasions. In his cases, which included furunculosis, carbuncles, acute adenitis, erysipelas, and other septic processes, the early fall in the temperature was a striking feature, while the general result was most satisfactory. Ferrari[3] claimed good results from daily doses of 0·01 gramme (g.) of mercuric chloride in influenza, which amounts to approximately 3·0 times my average dose. Pérez, of Madrid, quoted by Vecki, reported a most pronounced curative action from intravenous injections of mercuric chloride in puerperal septicæmia in doses of 10 c.cm. of a solution of 1 in 1000 (0·01 g.). Mello,[4] of Rome, injected 2·5 mg. of mercuric chloride intravenously twice during a period of 24 hours, then 4 mg. (1/16 gr.) at the same interval, for two consecutive days in three cases of puerperal fever which terminated in complete recovery. Nixon,[5] of Texas, states in reference to this method of treatment: "It has been revived from time to time, and each time abandoned, because obliteration of the veins has been produced." To avoid this complication he recommended that the patient's blood should be allowed to mix with the solution of mercury in the syringe, and then the mixture of blood and mercury injected. In his opinion, by this means the ill-effects of the perchloride were avoided, as shown by the results which he obtained in 50 cases without a mishap.

I am indebted to Captain D. C. Monro, R.A.M.C., surgical specialist at the Royal Herbert Hospital, for particulars of a case of septicæmia which he treated along the lines advocated by me with intravenous perchloride of mercury.

The patient, a gunner, aged 22, was admitted to hospital for a strangulated inguinal hernia; two days after operation he had broncho-pneumonia, and his condition was so bad that antistreptococcic serum was given and repeated to the extent of 120 c.cm. in 24 hours, without benefit. A bacillus of the influenza type was isolated from the blood stream. Two injections of perchloride of mercury were given intravenously within 48 hours, with very considerable benefit in the degree of toxæmia and with rapid fall of temperature terminating in complete recovery.

### *Technique.*

The method which I employ is to give 5 c.cm. of a 1 in 1250 solution of perchloride of mercury (1/16 gr.) in saline as a first dose and repeat the injection, if necessary, in 12 to 24 hours, according to the patient's condition. My maximum dose for one injection so far has been 7 c.cm. of 1 in 1250, and such dosage has been reserved for cases which did not appear to offer much hope of success at the outset of treatment, but in two of these cases, although recovery ensued, obstinate mercurial stomatitis developed. In my experience, if four injections given over a period of three days fail to produce definite improvement it is useless to continue with this line of treatment.

The perchloride solution is always freshly prepared and is injected directly into a vein which is rendered prominent for the moment. A little blood is allowed to flow into the syringe and mix with the mercurial solution and the mixture is then injected into the lumen of a vein.

### *Complications.*

*Thrombosis.*—In one instance only local thrombosis occurred as a result of the injection of perchloride of mercury. This patient was unconscious at the time of the first injection and was suffering from *Staphylococcus aureus* pyæmia. I have found that the dilutions of perchloride of mercury in saline which I have recommended are perfectly satisfactory and can be safely employed, provided none of the solution is injected until the blood flows freely into the syringe. The escape of perchloride into the wall of the vein or surrounding tissues will lead to thrombosis which may have serious consequences. Such cases have been recorded in the literature; in fact, the perchloride treatment has been abandoned by some because of thrombosis, tissue necrosis, and other ill-effects owing to faulty technique or from excessive dosage. If, however, every possible care is exercised during the intravenous inoculation of perchloride of mercury, the local risk is negligible. If thrombosis due to the infection has occurred before treatment is commenced, it *may* increase as a result of the mercurial injections, although I have risked this complication.

*Diarrhœa.*—This may be severe and occur within an hour or two of the intravenous injections. At the outset it may be beneficial, but early treatment must be adopted unless it is of a mild character. There may be as many as eight or ten motions in the same number of hours. In my experience, although the severe form of diarrhœa is very exhausting to the patient at the time, it appears ultimately to be of distinct advantage. The most efficient method of treating this complication is by means of salines with opium.

*Stomatitis.*—Twenty hours, or even less, after the intravenous injection of perchloride the gums may be painful, spongy, and red, and show a tendency to bleed. Small ulcers may form which are sometimes very intractable to treatment.

*Nephritis.*—The most dangerous complication is usually considered to be nephritis, but in spite of the large number of injections which I have given nephritis has not occurred. The urine should be examined before and during treatment. In those cases where there has been a large amount of albumin and casts, the perchloride treatment has not been attempted. Two cases of septicæmia were treated with mercuric chloride who had marked albuminuria, but the renal efficiency in each instance was regarded as satisfactory, and no ill-effects followed. Guillain and Gardin, in 1922,[6] reported a case of acute nephritis with cardiac failure from the intravenous injection of perchloride of mercury, and it is stated that mercury was present in the cerebro-spinal fluid.

### *Reactions, General and Local.*

The effects of the intravenous injections may be described as general and local. A slight rise of temperature may occur shortly after the injection of perchloride, and the patient, unless precautions are taken, may suffer from shiverings or true rigors; the temperature may then show a definite fall and may approach or reach the normal level within 24–48 hours, or further injections may be necessary. In some cases, although the progress of the disease appeared to be arrested, recovery was a very slow process. In many instances the fall of temperature was very striking and a marked diminution in the degree of toxæmia occurred which was readily recognised by the patient. When perchloride of mercury is injected intravenously in the early stages of an acute infective process there is a strong chance that improvement will occur, but as the duration of the acute illness lengthens, so the chance of improvement from perchloride diminishes. The chief local change has been arrest of the extension of the inflammatory process, more especially in spreading inflammation involving the face and neck, but when no general beneficial action of the perchloride occurs, there is no probability of arrest of the local process.

In one case of this kind the beneficial effects of the perchloride were very remarkable.

The patient, a man of 60, had a very extensive acute inflammatory process with considerable necrosis involving the upper and lower lip and neck due to the *Staphylococcus aureus*, and he was very toxic. Surgical opinion was opposed to surgical treatment. A diminution in the degree of toxæmia rapidly followed the intravenous injection of perchloride of mercury and the local spread of infection was arrested. A second injection was given of 1/12 gr., and resolution of the inflammatory process occurred.

In cases with closed abscess formation, perchloride of mercury intravenously is useless.

It is believed that this treatment is dangerous, because it is stated that the perchloride greatly depresses the activities of the polymorph, which, of course, is a serious objection. When the late Prof. S. G. Shattock and I were studying the variation in the phagocytic action of the polymorph in the blood in various acute and chronic infective processes, we found that in spite of a depressed phagocytic action of the cells in the blood, and a total reduction in their numbers, yet complete recovery from an acute infective process was possible. In some of the cases treated with perchloride of mercury the total number of polymorphs was reduced and their phagocytic activities depressed, subsequent to the injection of the perchloride, yet the infection was aborted and complete recovery ensued. A detailed record of the blood reactions following intravenous inoculations of perchloride of mercury and mercurochrome 220 will, however, be fully dealt with at a later date.

### *Mercurochrome 220.*

In 1919 Young, White, and Swartz[7] introduced a new preparation for the treatment of bacterial infections. Chemically it is the di-sodium salt of dibromoxymercury fluorescin. It is readily soluble in water and normal saline and is unaffected by moderate heat or exposure to air. It contains about 26 per cent. of mercury, and even 1 per cent. of this preparation does not form a precipitate with hydrocele fluid. The wide range of application of the drug in urinary and many other septic processes is fully recognised, but it is only the intravenous use of this preparation which is now under consideration.

*Toxicity.*—Young, White, and Swartz found from their experiments that 10 mg. per kilo invariably killed rabbits in 24 hours, while 5 mg. produced an albuminuria which lasted one week. Dogs tolerated 10 mg. quite well, but albuminuria occurred without rise in blood urea. It has been shown that alkaloids and certain local anæsthetics may be precipitated by mercurochrome 220. Kolz, quoted by Warren,[8] has recorded a case of poisoning owing to this incompatibility with procain.

### *Personal Experience: Mercurochrome 220.*

I have used this preparation intravenously in 150 cases of acute bacterial infections subsequently to, or instead of, perchloride of mercury, and have found it to be of definite value. Mercurochrome 220 dissolved in saline hæmolyses red blood corpuscles, but in the presence of blood serum or blood plasma the hæmolytic activity is considerably reduced. With washed red cells hæmolysis occurs with a dilution of 1 in 2000 in saline in vitro, while I employ for intravenous inoculations strengths of 1 in 200, 500, and 750 in saline without ill-effect.

I have given daily intravenous injections of mercurochrome for five days without observing any complications which could be credited to it, and possibly daily injections could be given over a longer period. The dramatic effect recorded on several occasions after one or two injections of perchloride of mercury, when the acute infective process was suddenly aborted, has never resulted from injections of mercurochrome. A shivering or true rigor which may follow an intravenous injection of mercurochrome 220, but especially perchloride of mercury, can be prevented, or greatly modified, by keeping patients warm during and after treatment and by giving about 10 gr. of aspirin with hot tea immediately after the inoculation.

In the report issued by the Medical Department of the United Fruit Company,[9] Dr. Deekes and his colleagues record their results with mercurochrome 220 soluble, administered intravenously. A 1 per cent. solution was employed almost entirely, and the dosage varied from 10–15 c.cm., which was repeated as required, but "with few exceptions (such as in patients almost moribund) there was a severe reaction in the form of chills, fever, vomiting, diarrhœa, and stomatitis. These untoward symptoms were of brief duration and differed considerably according to a variety of conditions." Various infections were treated and the results appear to have been satisfactory. Twenty-six cases of lobar pneumonia were inoculated intravenously with mercurochrome, with a mortality of less than 20 per cent., while in the same medical division the mortality from lobar pneumonia over a period of years was 49·13 per cent.

It will be noticed, however, that severe reactions complicated with stomatitis followed these inoculations. In my opinion these toxic symptoms can be explained by the strength of mercurochrome 220 employed for the injections. From personal experience 10 c.cm. of 1 in 200 of this preparation in saline is the maximum dose which should be given, and when the injections have to be repeated it is necessary to reduce the strength of the solution to 1 in 500 after two or three doses of 1 in 200 have been employed. Cases of nephritis with blood, albumin, and casts in the urine have followed injections of mercurochrome 220 in doses of 1 in 100.

The essential fact in the treatment of acute bacterial infections is the neutralisation of the bacterial action without damage of the tissues, but there is a tendency at the present day to concentrate on parasitic destruction without sufficient regard for the host. Some of the disasters which have followed the inoculation of so-called therapeutic remedies have been due to this cause. If acute nephritis is produced there is every possibility that other important structures may be similarly affected, although proof positive evidence may not be obtained during the life of the patient.

The cases treated by me with mercurochrome were similar to those treated with perchloride of mercury, although the fulminating and very severe cases mostly received perchloride of mercury at the outset, and were subsequently treated with mercurochrome 220 when necessary. This preparation can be given, as already stated, in repeated doses provided the correct dilution is employed. Sudden arrest of the inflammatory process did not occur with mercurochrome 220, but in a few instances the acute infective process was sufficiently improved that one or two intravenous injections were sufficient. In most cases four or five injections were necessary. In about 20 per cent. of the cases treated with mercurochrome, which were very largely of a less severe type than those treated with perchloride of mercury, no benefit occurred.

**BRADFORD HOSPITALS.**—As we recently announced, a new building for the Bradford Royal Infirmary is to be built at an estimated cost of £500,000. The scheme, which was initiated in 1009, provides for about 400 beds with the necessary adjuncts and all the most modern appliances, and will include a block of separate rooms for paying patients. There are at present 215 beds. The infirmary has been four times enlarged during the last 60 years—it has recently celebrated its centenary—but nearly 30 years have elapsed since the last expansion. The Bradford Corporation Mental Deficiency Committee propose erecting, at a cost of £179,000, a new institution to hold 700 patients. The North Riding County Council will take 100, and York Corporation and Huddersfield Corporation 50 beds.

# DETERMINATION OF THE BASAL METABOLIC RATE.

By T. C. HUNT, B.A. Oxf.,
OF THE SURGICAL UNIT, ST. MARY'S HOSPITAL, W.

THE standard method used almost universally in England for the estimation of the basal metabolic rate is by the Douglas bag and gas analysis. Although admittedly an accurate, and for physiological purposes an extremely valuable method, it suffers clinically from the drawback that it is a tedious and somewhat laborious estimation, and its technique requires considerable experience if error is to be avoided. For these reasons any simpler, easier, and more rapid method for routine clinical use, and one, moreover, that is capable of general employment in ordinary practice, without the necessity of laboratory aid, is clearly of the greatest value. Such an apparatus is that devised by Sanborn, the "Handy Metabolor,"[1] and this short investigation has been undertaken to see how far accuracy need be sacrificed in order to gain the advantages of speed and simplicity.

For this purpose parallel determinations have been made of the basal metabolic rate in a number of cases in the wards of St. Mary's Hospital both by the Sanborn and the Douglas bag methods, to decide how much trust may be placed in the results of the former as compared with those of the latter. For many reasons the exactly correct basal metabolic rate is an exceedingly difficult value to obtain, though clinically an error of 10 per cent. is not of great significance. With the Douglas bag method a really careful worker can obtain more accurate results than this, and therefore the values obtained by this method in the cases examined were taken as the true metabolic rates with which the Sanborn results might be compared.

### *Procedure: the Douglas Bag Method.*

In all cases the procedure was the same; the usual precautions were taken to exclude mental excitement, movement, &c., and all patients were in bed in the post-absorptive state. The "physiological" method was first employed, and an interval of 15–30 minutes was allowed before beginning the "clinical" determination, to avoid subjective psychic effects resulting from the first investigation. The determination by the Douglas bag method was carried out in the ordinary way, in most cases two samples at least of expired air being analysed in the Haldane gas analysis apparatus. It was found during the few preliminary investigations that a commonly unsuspected source of error could be traced to delay between filling the bag and taking out the samples for analysis (and measurement of the total volume). Although, of course, it was realised that such an interval must, if prolonged, lead to escape or alteration of the gas contents of the bag, it was at first thought—and many workers are constantly in the habit of doing this—that a full bag could with safety be left from, say, noon until evening before a sample for analysis need be taken out. A few determinations from an absolutely new full bag at hourly intervals showed that in even so short an interval a definite diffusion of carbon dioxide outwards occurred, so that regularly diminishing $CO_2$ values were obtained. This is a question of the solubility of the gas in the rubber lining of the bag, and occurs only very slowly (and negligibly) with oxygen. (This solution and diffusion may be strikingly seen if hydrogen is used in the bag.) This error is, of course, easily eliminated by taking a sample of gas from the bag as soon as it is filled into an evacuated sample tube, after which the analysis is carried out when convenient. The oxygen intake, $CO_2$ output, respiratory quotient, and hence the basal metabolic rate were determined, using Zuntz's tables of the calorie value of one litre of oxygen and Du Bois height-weight formula for the calculation of the surface area.

---

[1] Basal Metabolism. By F. B. Sanborn, 1048, Commonwealth-avenue, Boston, Mass., U.S.A. 1922.

### *The Sanborn Method.*

With the Sanborn method, taking, of course, the same care as to preparation, &c., the patient simply breathes in and out of a spirometer which is filled with oxygen and contains a soda-lime cylinder which absorbs carbon dioxide. The actual technique of the method is fully explained in Dr. Sanborn's book, "Basal Metabolism," and it is sufficient to say that the apparatus is portable, and that with very little experience both the actual determination of oxygen consumption and the calculation from this of the basal metabolic rate may readily be completed within 20 minutes. The inherent error in the method is that pure oxygen with no $CO_2$ is an abnormal substance to breathe (and in time becomes definitely toxic), and that the respiratory quotient is impossible to calculate and has to be taken as a constant for all individuals at an average figure of ·82. There is further a technical error, in that observations of oxygen consumption are not capable of being read to less than 25 c.cm., and that corrections for temperature and pressure are only approximately made. The first is not a very serious objection. It is found that if three-minute spells of oxygen breathing are observed, the first is higher than the second—up to 25 per cent.—the second still perhaps 10 per cent. higher than the third, but that further observations are then found to remain remarkably constant within the limits of the technique. This is clearly due to the simple solution of oxygen in the blood from the increased pressure of the gas in the lungs and, though leading to an initial apparent increased oxygen consumption, saturation soon occurs and no further solution takes place. Unequal ventilation of the lungs and previous undersaturation of the hæmoglobin of the blood will also lead to false high values, but these factors will normally cause but little or no error. (The alveolar $CO_2$ tension cannot, of course, be calculated in Sanborn's method, and though this is lowered in pure oxygen breathing, especially if any hyperpnœa from nervous influences exists (Hill and Flack), it is doubtful if over a short period the actual oxygen consumption is at all markedly altered from that occurring when ordinary air is breathed.)

As to the constancy of the respiratory quotient—a factor, of course, essential for the calculation of the basal metabolic rate—it at first appears to be a most serious objection that differences in this value, if they exist, cannot be determined. In my series the respiratory quotient varied from 0·78 to 0·91, though 69 per cent. had actual values between 0·80 and 0·84; it is certain that the Sanborn figure of 0·82 cannot be taken as the exact value for all individuals, but it is remarkable how little difference in the actual basal metabolic rate results from a fairly large variation in the respiratory quotient. As an example of this, an oxygen consumption of 220 c.cm. per minute gave by Sanborn's calculation with respiratory quotient 0·82, a basal metabolic rate of +33, but with the actual respiratory quotient as found in the Douglas bag method of 0·76, +31. Thus with a comparatively large change in respiratory quotient, an almost negligible error is introduced into the actual calorie output per square metre per hour. With regard to the actual observation error, the mean value of oxygen consumption per minute is obtained with very fair accuracy (∓5 per cent.) by taking the values of four three-minute spells of breathing; and neglecting a short preliminary period of one or two minutes.

### *The Two Methods Compared.*

The results in a series of 25 cases showed a surprisingly close agreement between the two methods. Cases were taken both of those suffering from thyroid deficiency or hypersecretion and of others regarded as normals who were in the wards for various other conditions. Of seven cases showing clinically no evidence of metabolic disorder, six agreed by both methods within 10 per cent. as having normal basal metabolic rates. The closeness of this agreement may be seen from a typical example.

Patient A. A., aged 53; weight 170 lb., height 73 in. Pulse 70, resp. 20. Suffering from slight prostatic enlargement.

*Sanborn:*

Corrected volume of oxygen consumed per minute (mean of four three-minute spells) .. .. .. .. = 263 c.cm.
Normal for patient .. .. .. = 260 c.cm.
Basal metabolic rate .. .. = Normal.

*Douglas Bag:*

$O_2$ consumed per min. at STP .. .. = 257 c.cm.
R.Q. = 0·83 (1 litre $O_2$ = 4·84 cals.)
Surface area .. .. .. .. = 2·1 sq. metres.
Cals. per hr. (15,420 c.cm. oxygen) .. = 74·6.
Cals. per hr. per sq. m. surface area .. = 35·5.
Normal for patient .. .. .. = 38 cals.
Basal metabolic rate .. .. = −5.

Of these six normal values, five had a Sanborn value above that of the Douglas bag value, though within 10 per cent. of the latter. Of the other two cases giving normal Douglas bag values, one was 8 per cent. lower and one 17 per cent. lower as found by Sanborn's method. Of 15 cases with clinical evidence of hyperthyroidism, the basal metabolic rate by the Douglas bag method varied between +11 and +108; in nine of these the Sanborn gave values above those of the Douglas bag within 15 per cent.; three gave values within 10 per cent., lower than the Douglas bag; and three gave values one 28 per cent., one 31 per cent., and one 60 per cent. above the Douglas bag values. In three cases when the Douglas bag value was below normal (one of frank myxœdema) the Sanborn gave in two, values higher by 9 per cent. and 21 per cent., and one lower by 4 per cent. Thus of 25 cases, four only, or 16 per cent., varied more than 15 per cent. from the Douglas bag result. Of the remaining 21, 16, or 75 per cent., gave values between 0 per cent. and 15 per cent. higher than the "true" value—average 11 per cent. Twenty cases of the total 25 were within 12 per cent. of the Douglas bag value (5 below, 15 above), or 80 per cent., and of these 75 per cent. were values too high.

Thus, though these results were obtained over a small series of cases, the conclusion may be drawn that the Sanborn method is accurate within clinical demands—∓12 per cent.—in 80 per cent. of cases, and that the error, if any, is in 75 per cent. of cases, one of too high and not too low a value.

I should like to express my thanks to Prof. C. A. Pannett, of the Surgical Unit, St. Mary's Hospital, at whose suggestion this paper was undertaken, for the help he has given me throughout the investigation.

# BLOOD TRANSFUSION.

## A PLEA FOR THE DEFIBRINATION METHOD.*

By ROBERT PLATT, M.D. SHEFF., M.R.C.P. LOND.,
MEDICAL REGISTRAR, ROYAL INFIRMARY, SHEFFIELD.

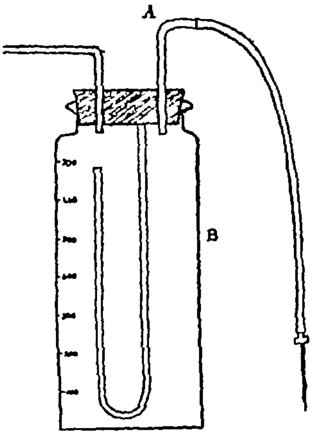
THE two great hindrances to the progress of blood transfusion in the past have been: (1) reactions following the introduction of incompatible blood; (2) the rapid coagulation of blood removed from the vessels. The first difficulty was solved by Jansky[1] and Moss[2] with the discovery of the blood-groups. Many attempts have been made to solve the second, the most convenient solution being the use of citrated blood, first introduced in 1914.[3] The last 11 years, however, have taught us that there is now another difficulty—namely, the "citrate reaction." The symptoms which commonly follow the introduction of citrated blood are a rise in temperature, rigors, and a feeling of general malaise, often accompanied by headache. They occur in at least 20 to 40 per cent.[4] of citrate transfusions—some observers say 60 per cent.[5] or even 70 per cent.[6] The reactions are not due to agglutination or hæmolysis, and hæmoglobinuria never occurs.

The early advocates of the citrate method made light of the symptoms, and rightly so, for by popularising blood transfusion, as a therapeutic method, there is no doubt that many lives have been saved. On the other hand, the symptoms of the reactions are always disturbing, sometimes definitely prejudicial to the recovery of the patient, and have been known to be fatal.[4] That the reactions are due to the citrate and not to the many other factors which have been suggested is shown by the fact that such reactions practically never occur when whole blood is used—and as I hope to show later, when defibrinated blood is used; by the case recorded by Keynes,[7] in which the donor himself, having received some citrate developed a reaction; and by the experiments of Drinker and Brittingham,[8] who showed that citrated red cells, thoroughly washed, might be toxic even to the individual from whom they were taken.

---

* A paper read before the Chirurgical Club at their Sheffield meeting, Oct. 1st, 1925.

FIG. 1.



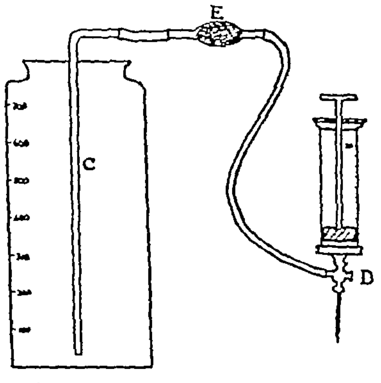
Apparatus arranged for collecting and defibrinating the blood.

My plea is that the final problem of blood transfusion has now been solved by the introduction of a method if anything more simple than the citrate method, and practically free from reactions. I refer to the use of defibrinated blood. This was first employed as long ago as 1835,[9] but we owe to Colebrook and Storer, who published their paper in 1923,[10] the introduction of the present simple technique. My own method is merely a modification of theirs, in most essentials identical, but I think slightly more simple. However, since defibrinated blood is still but rarely used, the method will be briefly described.

*Technique.*

1. *Collecting the Blood.*—A wide-bore needle, connected to about 12 inches of rubber tubing, is inserted into the donor's vein. The tube leads through the glass connexion (A) into the jar (B) (Fig. 1). A glass rod, bent in the shape of a U, protrudes from the under surface of the rubber bung, and must all but touch the bottom of the jar. The blood is allowed to flow into the jar by gravity, and as soon as the first few c.cm. are collected, an assistant shakes the jar briskly in such a way as to keep the blood rotating round the U-shaped rod. This rotation is kept up the whole time that the blood is being collected, and for *at least six minutes afterwards.* All the fibrin collects on the rod, the rest of the blood remaining permanently fluid. Instead of the usual tourniquet on the donor's arm, a blood-pressure armlet pumped up to about 80 mm. of mercury ensures that the veins, but not the arteries, are obstructed. A suction bulb may, if desired, be attached to the second tube leading into the jar. This tube is otherwise only necessary as an air outlet.

FIG. 2.

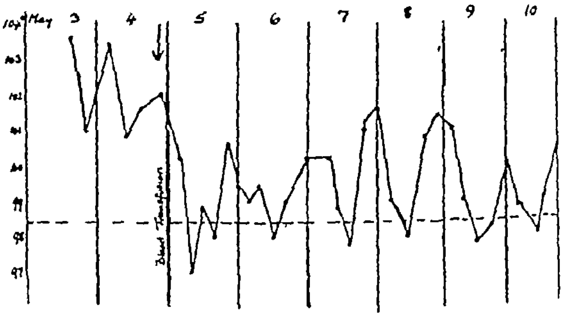


Apparatus arranged for injecting the blood.

2. *Injecting the Blood.*—The rubber bung and its attached tubes are removed from the jar, and with them the U-rod and adherent fibrin. The long glass tube (C) (Fig. 2) is then inserted into the jar. This is connected by a rubber tube to the two-way tap (D), but the rubber is interrupted by a small glass bulb (E) which contains *glass*-wool to act as a filter for possible small clots. The tap (D) is connected with a syringe at one end, and with a needle or cannula at the other. Before inserting the needle or cannula, the whole system is, of course, filled with blood by suction from the syringe. The blood from the jar is then injected in successive syringefuls, the tap being turned alternately to fill from the jar, or empty into the vein. In the majority of cases it is easier in the long run to dissect the vein of the recipient under local anæsthesia, and use the cannula. The syringe, tap, needles, and cannulæ all have "Record" mounts, and are interchangeable. With the exception of these parts, the whole apparatus can be made in any laboratory, but the Medical Supply Association can supply the whole apparatus, or any part of it.

Colebrook and Storer brought out their method for the purpose of giving immunised blood. They claim that by immuno-transfusion many cases of septicæmia are benefited, the temperature actually falling after transfusion. I have never tried immuno-transfusion, but I have had several results which I think are as striking as theirs. The chart shown in Fig. 3 is from a case of septicæmia and secondary hæmorrhage from a septic wound of the leg; 200 c.cm. of the patient's blood were removed by venesection, and replaced by 500 c.cm. of defibrinated blood. He made a very good recovery. In 34 consecutive transfusions I have not had a single symptom of a reaction, nor a rise of temperature in a previously afebrile patient. Colebrook and Storer, in a later paper,[11] record a similar freedom from reactions, again referring to immuno-transfusion.

FIG. 3.



Temperature chart before and after transfusion.

In the course of the series, I have given most of the combinations of blood-groups that are compatible—namely, IV. to IV.; IV. to III.; IV. to II.; IV. to I.; III. to III.; II. to II.; and II. to I. The cases include several of pernicious anæmia transfused more than once. In septicæmia, pyæmia, bacterial endocarditis, and other febrile states there is usually a fall of temperature and clinical improvement, which, however, in severe cases is only too often temporary.

*Conclusions.*

1. The disadvantage of transfusion with citrated blood is the frequency with which "reactions," often mild, sometimes serious or even fatal, follow the introduction of the blood. 2. In 34 consecutive cases transfused with defibrinated blood no such reaction occurred. 3. The defibrination method is, if anything, the simpler of the two. 4. The defibrination method therefore deserves much greater popularity than it has yet received. If, after extended trial, it still proves satisfactory, the citrate method should be abandoned as obsolete.

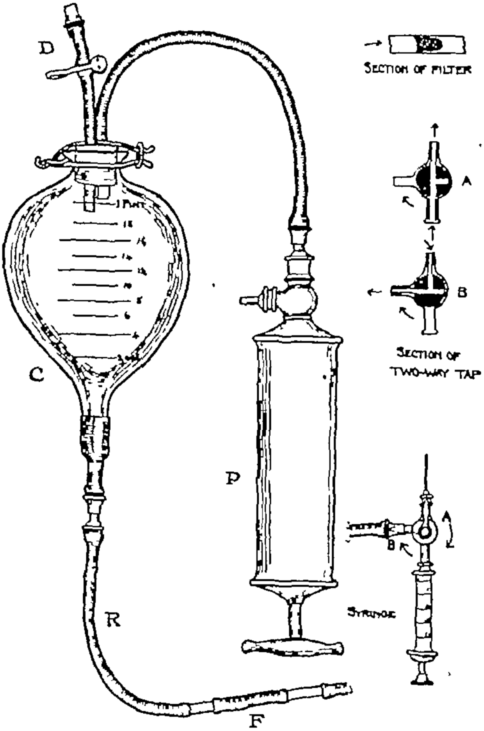
# A BLOOD TRANSFUSION APPARATUS.

## INTRODUCING THE USE OF "RECORD" SYRINGE NEEDLES BOTH FOR THE DONOR AND THE RECIPIENT.

By H. H. MOLL, M.D., M.R.C.P. LOND.,
MEDICAL TUTOR AND REGISTRAR, UNIVERSITY OF LEEDS.

THE following apparatus has been devised for transfusing citrated blood with "Record" syringe needles. The method briefly consists of aspirating the blood from the donor's vein into a glass container and of pumping it into the recipient's vein through a fine needle.

The transfusion bottle is shown in the accompanying diagram, and consists of a pear-shaped glass container, closed at one end by a rubber stopper fitted with an air-inlet tube (P) and a shorter tube (D) which collects the blood from the donor. After having collected the blood, a long tube (R) is attached to the lower end of the container and conveys the blood to the recipient. It is provided with a filter consisting of a thimble of fine wire gauze inserted inside the tube between two glass connexions. The apparatus is also provided with a powerful suction and pressure pump and with a two-way stop-cock; the former is attached to the air-inlet tube, the latter to tube (D) or (R), and is fitted with a needle and a syringe. By means of this stop-cock the operator may first ensure that the needle is inside the vein by drawing off a little blood into the syringe, and then by a quick turn of the tap divert the flow of blood into the container, or into the recipient's vein, as the case may be. This eliminates unnecessary delay in connecting the apparatus to the needle after the vein has been punctured and prevents blood clotting inside the needle. A thick and short (1 in. long) exploring needle is used for collecting the blood from the donor, whilst a very fine needle (such as is used for intravenous injections of galyl) is used for transfusing the blood into the recipient's vein.



The blood transfusion apparatus is shown ready for transfusing blood into the recipient. P, Suction and pressure pump connected with container, C. D, Inlet tube from donor (clipped). F, Filter. R, Outlet tube to recipient (the two-way stop-cock, syringe, and needle have been attached to the distal end).

### *Technique.*

The required amount of a freshly prepared 5 per cent. solution of sodium citrate is aspirated into the container. The mixture of citrated blood should not contain less than 0·5 per cent. sodium citrate (i.e., for a pint of blood 2 oz. of a 5 per cent. solution are required). The two-way stop-cock, fitted with the syringe and needle, is attached to the inlet tube (D) with the tap turned in such a way as to have the needle and syringe communicating. Having punctured the vein of the donor, the operator withdraws some blood into the syringe (thus ensuring that the needle is inside the vein) and then turns the tap and allows the blood to flow into the container. The flow of blood is assisted by means of the aspirating pump and by instructing the donor to clasp and unclasp his fist alternately. Only a very slight negative pressure is required, as too much suction is liable to collapse the walls of the vein. A tourniquet should have been placed around the upper arm of the donor, tight enough to obstruct the venous blood, but sufficiently loose to allow the radial pulse to be still felt. After having withdrawn the required amount of blood, tube (D) is clipped, tube (R) is attached to the lower end of the container, and a little blood is allowed to be run through in order to expel all the air contained therein.

The procedure of transfusing the blood into the recipient's vein is similar to the one described above when collecting the blood from the donor, but the tourniquet has to be unloosened as soon as the vein is punctured. A fair amount of pressure is required in order to maintain a steady flow of blood through the very fine needle.

This method of blood transfusion is easily carried out at the bedside and does not require any local anæsthetic. The same vein may be used repeatedly when blood transfusions are required at frequent intervals, such as in the treatment of pernicious anæmia.

Mr. Charles F. Thackray, Great George-street, Leeds, is the maker of the blood transfusion apparatus.

# ERYTHRŒDEMA OR PINK DISEASE.*

BY C. P. LAPAGE, M.D. MANCH.,
F.R.C.P. LOND.,
LECTURER, DISEASES OF CHILDREN, UNIVERSITY OF MANCHESTER; PHYSICIAN, ROYAL MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY; PHYSICIAN FOR CHILDREN, ST. MARY'S HOSPITALS, MANCHESTER.

THE condition about to be described has lately made its appearance in Great Britain, and occurs in young children. It has been called erythrœdema, erythrœdema polyneuritis, acrodynia, and pink disease. The characteristics are fairly sudden onset in a healthy baby, beginning with irritability, insomnia, and loss of appetite. A miliary rash appears, followed by the development of the characteristic pinkness of the hands, feet, and face, and marked hypotonia of the muscles. Symptoms resembling meningismus appear, and the child becomes intensely miserable with photophobia, gingivitis, and dropping out of the teeth. Death may occur very suddenly as the result of weakness or terminal infection, or the child may make a slow recovery and return to complete health.

### *History.*

Early in 1921 Wood[1] described this disease. He mentioned that Swift, of Adelaide, had read a paper in 1914 at the Tenth Australian Medical Congress at Auckland, founded on notes of 14 cases. The disease has, therefore, been recognised in Australia for a long time. More recently there have been many articles in America describing this disease, chiefly under the heading acrodynia. A good summary is given by Rodda,[2] in which he mentions that Bilderback in 1919 reported ten cases. In THE LANCET[3] in 1918 a summary of Swift's article is given. This was followed by a note on similar cases by Doak. Doak's cases are not fully described, but some may have been pink disease, though three of them gave a positive Wassermann. They occurred in the Infants Hospital, Bradford. Swift stated that he had seen cases of the disease when he was in London, and Parkes Weber demonstrated a case which was probably one of severe erythrœdema in 1921, and described it as pink disease in 1922. Thursfield and Paterson described a case in 1921–22, and Paterson and Greenfield gave a complete account of the disease[4] in a report of post-mortem examinations on two fatal cases. They use the name erythrœdema polyneuritis because there was distinct evidence of polyneuritis in the autopsies in their two cases. Fowler's article also gives a detailed account of the disease with reports of four cases. In other parts of Europe not much attention has yet been given to the disease, though it has occurred. Comby in France reported a case in 1922, and Feer and Keller in Germany. In Manchester cases have been met with for some three years. The first case which I recognised as pink disease was seen by me in May, 1923, and in June, 1925, I showed some cases at a clinical meeting of this society. From my own experience I have no doubt that a considerable number of cases have been occurring in and around Manchester for the past two or three years, and in many instances have not been recognised.

### *Detailed Description.*

A baby from 1 to 3 years old, who has previously been well, becomes from no apparent cause irritable, loses appetite, sleeps badly, and begins to whine and cry. Marked perspiration and a miliary (sweat) rash develop, and the infant becomes steadily weaker. Then, often quite suddenly, his hands and feet become red and swollen, and take on the characteristic pink appearance. The rash continues to appear, sometimes with small pustules, and in most cases desquamation occurs, noticeably at the edges of the pink areas. The pink appearance may spread to the cheeks and nose, and that in the hands and feet usually assumes a deeper and blue colour. In the later and recovery stages of the disease rather remarkable variations of this phenomenon occur; thus for some days the extremities will be merely a light pink and for others they will be cold and blue and have the appearance of a very large chilblain. The child is generally distressed because the hands and feet prick and burn, and he may try to alleviate this by rubbing or even biting the affected parts. Symptoms of head irritation may now appear, giving rise to a suspicion of meningitis, but they go no further than the signs described as those of meningismus. There is no real retraction of the head, but there is much irritation, because the child moves the head from side to side, and often pulls out the hair until he has bald patches.

Photophobia may be a very marked symptom causing the child to bury his face to avoid the light, thus adding to the picture of cerebral irritation and abject misery presented by the case. This appearance is further increased by the hypotonia of the muscles, as a result of which the child lies in a characteristic position of inertia, or sits up in a position of atonia with drooping shoulders, gaping of the mouth, and drooping of the eyelids. There is wasting with muscular weakness and paresis, the knee-jerks are diminished, and in some cases sensation may be impaired. But it is difficult to test for this because the child is so young. The hair becomes dry and wispy. Salivation occurs, and perhaps nasopharyngitis. Gingivitis may make its appearance, and go on to dropping out of the teeth. This is sometimes rather a striking feature of the case, and I have known it to be taken as evidence of a possible specific origin. It is usually a very troublesome complication, and the cause of much anxiety to parents and medical attendant. Ulcers of the mouth are not rare. If other special examinations are made the pulse is found to be rapid, the blood pressure very high, 100–120. The blood shows, according to Brown, a polymorpho-nucleosis, and, according to Fowler, a leucocytosis. Wassermann tests have been negative; the cerebro-spinal fluid has been negative, except in one case where Blackford reported an increase of globulin. The urine may show pus, but pyelitis may be the common complication of any such asthenic condition in a child. Several of my cases in the later stages when they were recovering had a curious golden-orange tinted urine.

We call the disease erythrœdema, but the œdema is not always very marked to external examination; there is, however, no doubt that it does occur. Thus Butler reports a section of the skin to show the intense hyperkeratosis and much œdema. The pinky-blue appearance of the extremities remains a very marked feature of the case throughout the long course of recovery; it comes and goes, the variations not always seeming to be related to chilly atmospheric conditions but more to some nervous control. This is suggestive, in view of the theory that the sympathetic nervous system is affected.

The progress of the case is, in my experience of 12 cases, usually favourable, but there are quite a number of fatal results. If the case is going to improve, there is after one or two months a gradual improvement in the general health. The child begins to take more interest in his surroundings, sleeps better, takes more food, and the symptoms begin to abate. The period of convalescence is long, and may last for one or two years, but recovery is complete. Not all cases, however, proceed to a favourable termination; quite a number of cases have been reported as dying suddenly with no apparent cause, others die by a terminal infection, or by the process of gradual exhaustion. There is no definite evidence yet as to the reason for sudden death.

### *Ætiology.*

Age: In most cases this disease occurs in young children between 1–3 years. Rodda reports a case at the age of 7 years. Sex: Both sexes are equally affected. *Season*: Most cases occur in the early spring or summer, and it has been suggested that the disease follows outbreaks of influenza of the spring before. *Distribution*: There is as yet no evidence of cases coming from any one area. My cases came from widely separated areas though most of them were from south Manchester. The history of the disease seems to show that it occurred first in Australia, then in America, and then in Europe. It certainly seems to be a new disease here. I can remember during the last 20 odd years occasional cases of a very similar nature which we then called *meningismus*, but I have no notes or recollections of having seen the characteristic pink appearance of the extremities. If the disease is not new it has certainly increased very much in this district in the last three years.

[2] American Journal of Diseases of Children, August, 1925.

[3] THE LANCET, 1918, i., 611.

[4] Quart. Journal of Medicine, 1923–24.

There are several theories as to causation; one of the most likely is that it is an infective disease. Many observers report nasopharyngitis; some have found diphtheroid bacilli. Hess reported a case with ulcer of the pharynx leading up to mediastinal abscess as evidence of relation between the disease and local sepsis. Vipond reports two cases with adenopathy in which he isolated a Gram-positive diplococcus from the glands and administered a vaccine with good results in both cases. Paterson and Greenfield report a definite polyneuritis, affecting particularly the peripheral parts of the nerve trunks, with diffuse increase of small cells in the grey matter of the central nervous system, especially of the lumbo-sacral enlargement of the cord. There were also grave changes in the motor nerve cells of the ventral horns, particularly those supplying the distal portions of the limbs. But they state that they have no clear evidence of microbial invasion, though they think it likely. Blackford reports an autopsy in which evidence of encephalitis was found.

The rash is very like a septic condition, and I have made many attempts to obtain an organism from the pustule, but it is very difficult to find any actual pus, and I have only twice succeeded in obtaining a staphylococcus which was probably a skin infection. Several observers report cultural examinations of the blood, but up to the present they have been negative. Other observers report a very great improvement from removal of the tonsils and from intranasal treatment. Others, again, report very good results from artificial sunlight treatment which is most efficacious in septic conditions. Another possible theory is that it is a deficiency disease, and investigations have been carried out to see if diet had any effect, but most observers have come to the conclusion that the disease is not a deficiency one. Three of my cases were breast-fed at the time of onset. The trouble in the hands and feet very closely resembles that of a chilblain, and, in fact, many of the symptoms of the trouble might, as suggested by Feer, refer to disorders of the vegetative nervous system. These are salivation, rapid pulse, insomnia, mental depression, and the characteristic pinkness and œdema.

### *Nomenclature.*

It is necessary to decide what name we shall give to this disease. At present there are the following to choose from—erythrœdema (Swift), (Wood), acrodynia (American), pink disease, erythrœdema polyneuritis (Paterson and Greenfield). The child certainly suffers from pinkness and usually from œdema, though this is not always very evident externally. I think that erythrœdema is a better name than acrodynia. Acrodynia means painful extremities, but it has already been used to describe an epidemic of acute infective polyneuritis which occurred amongst French soldiers, and it is a pity to transfer it to this disease. Many observers in America have adopted this term, but Butler and Bilderback do not agree with it. We have not yet sufficient evidence to say that polyneuritis occurs in all cases, and therefore it is doubtful whether we should add the word polyneuritis.

The name pink disease is an arresting description, and I think it is likely to hold. It is certainly useful in attracting attention to the disease to make it more fully recognised. We can therefore call the disease erythrœdema or pink disease.

### *Clinical Reports.*

The following is a brief summary of notable points in 12 cases of pink disease which have recently occurred in my practice.

The first case was seen in May, 1923, the next four in 1924, two in June, one in July, one in September, and the next seven in 1925. March, April, May, two in June, July, and September. These dates refer to the onset of the disease The disease, therefore, seems to occur in the late spring and early summer. The ages of onset were, three under the age of 1 year, all being breast-fed babies, and the rest under the age of 3 years; eight were boys and four girls.

With regard to the district in which the disease arose, seven were in the south side of Manchester, but were in widely scattered areas, as follows: Rostherne, Altrincham, Ashton-on-Mersey, Stretford, Rusholme, Chorlton, and Didsbury. There were cases also from Patricroft, Irlam o' the Heights, Bolton, and Hyde.

With regard to symptoms and signs, in two cases the bowels were loose and slimy at onset. All of the children had a decided rash, in only three was œdema a marked sign. In three of the cases there was a history of pulling out of the hair Five of them had marked photophobia, and in one Dr. H V. White, of the Eye Hospital, reported phlyctenular conjunctivitis and keratitis. In three cases there was history of nasal discharge, but in others there was no nasal discharge. Neuritic pains were present in one case. Ulceration of the gums was present in three cases. In two the teeth fell out, and in one there was a definite mouth ulcer inside the lower lip. One case developed intussusception in the course of the disease. It should be noticed that one of Paterson and Greenfield's cases died of intussusception. In at least eight cases there were decided signs of meningeal irritation. Chest signs in the form of bronchitis were present in two cases. The temperature was raised early on in the disease to 100° or 101° F. in four cases. The urine showed pyelitis in one case and in one marked deposit of urates, and in three in the later stages there was the definite golden colour. This sign is very noticeable when it is present. Blood culture (Dr A. Sellers) was negative in one case. Swabs of pustules showed staphylococci in two cases, but these were regarded as skin infections.

With regard to treatment, open air, good hygiene, and generous diet were most effective; artificial sunlight did good in one case, and in all cases gastro-intestinal disinfection seemed to have effect. Tuberculin injections were given in five cases; in some cases they appeared to have a decidedly beneficial effect. All the 12 cases have made a good recovery.

### *Differential Diagnosis and Treatment.*

The disease may be mistaken for (1) toxic œdema following gastro-enteritis, (2) meningitis, (3) multiple neuritis, (4) mental defect, (5) general tuberculosis, (6) congenital syphilis, (7) Raynaud's disease, (8) erythromelalgia, (9) rheumatism with sweat rash, and (10) pellagra. But in none of these is there the characteristic persistent pinkness of the extremities. Congenital syphilis gives the mouth signs and a rash, but not the pink extremities. The œdema of toxic œdema is much more pronounced and generalised. Once the disease has been noted it is easily recognised again.

Many observers in discussing the treatment deplore the fact that little can be done, but every effort should be made to relieve symptoms and promote recovery. Treatment should be directed to keeping up the strength, to relieving symptoms, and to trying to find some specific curative agent. Rest under good hygienic conditions is very important. The child must not be chilled too much, but, as the disease usually occurs in the summer time, open-air treatment can often be carried out. I have found this to help cases very much, especially if sunshine is available. With due attention to the bowels and digestion a generous diet should be given, especially during the misery stage. The nurse should attempt to persuade the child to take food. Tonics like cod-liver oil emulsion and nux vomica can be used. Paterson and Greenfield recommend small doses of arsenic. Thyroid does not do good.

The skin symptoms are chiefly those of the rash and irritability. Sweet recommends a dusting powder, with oxide of zinc, starch, and boric acid, together with silk clothing; Field a daily bran bath. I have used an ointment of sulphur and carbolic ointment equal parts mixed. Wood recommends painting of the fingers and toes with tr. iodi.

Another possible means of relief is calcium lactate internally, on lines similar to the treatment of chilblains. The gums may be very sore, and in my first case, before I recognised the disease, I had ordered grey powder in fairly large doses owing to the possibility of specific origin. The medical attendant and I had a discussion as to whether the stomatitis was a mercurial one or a specific one. However, we persisted in the grey powder, and, I think, it had a beneficial effect. Cleanliness and soothing applications are useful. Fowler recommends painting the gums with 1 per cent. chromic acid. The acute misery and hypotonia are a very troublesome complication, especially as they are usually coupled with insomnia. Only general measures will have much effect on this. I have not found that meningeal signs are relieved by lumbar puncture in these cases. The insomnia is best treated by open-air and artificial sunlight or real sunshine, by alleviating irritation, and by soporifics such as antipyrin, dial, and bromides, but it is not easy to make much impression on it in the worst stages of the disease.

The nasopharynx should be cleared if there is any evidence of infection; Rodda claims that removal of the tonsils should be carried out in every case, and that it has a remarkable effect in shortening the duration of the disease. If the bowels are at all upset a gastro-intestinal disinfectant should be used. The photophobia is curious and it was this that led me to try tuberculin. Having had several cases of photophobia which have improved very much with tuberculin, I tried it in one of these cases before I knew what the disease was. It was tried in five cases and it did good in four of them. It is not suggested that the disease is tuberculous in origin, but it is suggested that tuberculin has an effect in shortening duration in some cases. The urine must be examined for pyelitis and suitable treatment adopted.

Sweet claims very good results from artificial sunlight. I have tried this in some of my later cases, but have not noticed the very rapid cure which he claims for it; still it is likely to be a remedy of value. It is important to warm the limbs before the exposure.

*Specific Treatment.*—Attempts can be made to obtain an infective agent from nasal secretions or pustules, or from the blood. But pustules are scarce and most of my cases had no nasal discharge. Vipond took cultures of material aspirated from affected glands in two cases and had a vaccine prepared with very beneficial results in each case.

The bibliography of the disease has already attained considerable proportions, as can be seen from the following references, some of which are quoted from the lists given by others.

# Clinical and Laboratory Notes.

## A CASE OF ANEURYSM OF A SINUS OF VALSALVA BURSTING EXTERNALLY.

BY J. H. SHELDON, M.D., M.R.C.P. LOND.,
HON. PHYSICIAN, WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.

WHILE it is common enough for an aneurysm of the arch of the aorta to rupture externally, this accident is an exceedingly rare termination in the case of an aneurysm originating from the sinuses of Valsalva, the commonest rupture in this case being into the pericardium. Intrapericardial rupture was prevented in the case now described by the presence of a coexistent adherent pericardium, probably of rheumatic origin.

The patient, a man of 49, acquired syphilis in 1895 when in India. He received mercurial treatment, and had no other illness till the end of 1911. He was then serving in the army in France and he had an illness diagnosed as rheumatic fever, and was in hospital for three months. This left him with a "slight murmur," and his sheet was marked "D.A.H." He was discharged in 1919 with a pension on account of V.D.H. Since then he had worked almost without interruption as a packer in a motor-cycle factory.

Two years ago, while watching a football match, he suddenly felt "a stiffness across the front of his chest," which developed into a pain that prevented him from walking home. It soon passed off, and he was able to work for a year, complaining only of occasional attacks of pain on the top of the right shoulder and on the front of the right chest. In July, 1924, a swelling appeared in the region of the right nipple and below. It was moderately painful and for the first time he was obliged to cease work. He resumed work again after five weeks in bed, the swelling being still present. In December, 1924, a soft pulsating swelling—quite separate from the first swelling—appeared in the mid-line of the sternum at the level of the sixth costal cartilage. This was diagnosed as a gumma, and he was sent to the V.D. department. W.R. was positive. Dr. G. Mitchell, in charge of the V.D. department, noted that the pulsating swelling over the sternum—of the size of a thrush's egg—was surrounded by a triangular area of skin over the lower half of the sternum, which showed well-marked syphilitic mottling. He was treated with iodides and injections of Luetol, and improved so much that by the sixth injection the swelling had entirely disappeared, though pulsation could still be seen and felt where it had been. He left off treatment, but three months later, in May, 1925, the swelling reappeared, and on May 25th the skin over it broke, a mass of pulsating blood-clot appearing. He was then transferred to me and admitted to hospital. During all this time since July, 1924, he had continued at work without interruption, suffering no pain and feeling no discomfort.

*Condition on Admission.*—On the right side of the chest there was a firm rounded swelling, with very slight pulsation, involving the third, fourth, and fifth costal cartilages, extending from the nipple line to the border of the sternum. The lower half of the sternum was covered by a triangular area of discoloured skin, and in this, opposite the ends of the sixth costal cartilages, was a round hold half an inch in diameter, filled by a mass of pulsating blood-clot, from which there was slight oozing of blood. The heart was enlarged, the apex beat and the cardiac dullness on the left reaching to the nipple line in the sixth interspace. The upper limit of cardiac dullness was normal. On the right the limits of dullness were normal over the first two spaces, but below them the cardiac dullness was continuous with that produced by the rounded tumour. There was, therefore, continuous dullness from nipple to nipple. Heart sounds: double aortic murmurs, conducted in the usual directions, and audible over the rounded swelling. At the apex there was a long systolic bruit, conducted to the axilla, followed by a long rumbling bruit occupying the whole of diastole. No thrill was felt. Pulse 72, regular, of well marked Corrigan type. Blood pressure 210/80. There was no pain or dyspnœa, and he could sleep well in any position. This condition remained the same, except that the oozing of blood from the hole slowly increased until June 10th, 1925. On this date there was a sudden severe hæmorrhage from the hole, which was eventually stopped by pressure. On the following day the aneurysm burst through the hole, causing death in about two minutes.

*Post-mortem Examination*.—All the organs were normal, except the heart and great vessels. The pericardium was very large, and was firmly adherent in front to the sternum and to the costal cartilages of the third, fourth, and fifth ribs on the right side. The pericardial cavity was completely obliterated, the two serous layers of the pericardium being united by dense fibrous adhesions. The right auricle and right ventricle and their valves were normal. There was well-marked hypertrophy of the left ventricle, but there were no vegetations or signs of old endocarditis on the mitral valve. The aortic valves showed profuse changes of syphilitic character, being fused at their base, shortened, and the edges thickened into a nodular roll. The sinus of Valsalva by the anterior cusp was expanded out to form a saccular aneurysm of circular shape, the entrance to the aneurysm having a sharp edge surrounded by great hardening of the aorta. The aneurysm, which was entirely intrapericardial, had passed anteriorly to the right auricle, becoming firmly adherent to it, and had then pushed its way through the pericardium, lying beneath the sternum, finally perforating the latter through a hole half an inch in diameter. The chief mass of the aneurysm had spread to the right, causing the large rounded swelling seen clinically, under which, at the post-mortem, the pericardium was firmly adherent to the chest wall. Beyond the aneurysm the aorta showed patches of syphilitic aortitis, but was otherwise normal.

The obliteration of the pericardial cavity, presumably as a result of his attack of rheumatic fever in 1914, had evidently prevented an intrapericardial rupture, as is common in this class of aneurysm. The aneurysm had pushed the anterior half of the pericardium against the chest wall, caused the two to adhere, and had then perforated externally through the pericardium lying beneath the sternum, and finally through the sternum itself.

# FAMILIAL NEURO-SYPHILIS WITH APPARENTLY HEALTHY PARENTS.

By A. G. DUNCAN, M.D. LOND.

THE following personal and family record illustrates several interesting points which bear on congenital syphilis.

D. X., the patient whose illness led to an investigation of the other members of her family, came under observation in 1921, when she was 22 years old. In the previous August, on ceasing work for the summer holiday, she had complained of general malaise, occasional vomiting, and slight deterioration of memory. The first sign of any serious ill health was a severe and prolonged epileptiform fit, after which she was somewhat confused for a few days, and was then apparently well. On admission to hospital in November, 1921, she was mentally dull, lacking in attention, and emotionally unstable. The only physical signs of disease were a slight tremor of the lips, marked sluggishness of light reaction in the left pupil, and absence of tendon reflexes. Shortly after admission she had a series of fits resembling status epilepticus, and her mental condition considerably deteriorated. A positive Wassermann reaction in the blood, and the presence in the cerebro-spinal fluid (C.-S. F.) of 105 cells per c.mm., a positive Wassermann reaction, and the paretic type of colloidal gold reaction confirmed the diagnosis of dementia paralytica.

Her parents, brothers, and sisters were seen and examined clinically and serologically for any evidence of disease. The following notes give the record of the whole family.

*Family Record*.—R. X., the father; no symptoms; physical examination negative; W.R. negative in blood and no abnormalities in C.-S. F. on two occasions.

D. X., the mother; no symptoms; physical examination negative; W.R. negative in blood and C.-S. F. normal on two occasions. She had seven pregnancies:—

1. A., male, born 1891. Died in a mental hospital of dementia paralytica at age 26.
2. B., male, born 1896. No symptoms; physical examination negative; W. R. negative in blood; C.-S. F. normal.
3. D., female, born 1899. The patient described above.
4. F., male, born 1900. No symptoms; physical examination negative; W. R. negative in blood; C.-S. F. normal.
5. S., male, born 1902. Occasional headaches since receiving a blow on the head when 10 years old. Physical examination negative; W.R. positive in blood. C.-S. F. 12 cells (small lymphocytes) per c.mm., protein not in excess, W.R. negative, colloidal gold curve 001110000.
6. Miscarriage at sixth week in 1904.
7. H., female, born 1906. No symptoms; physical examination negative, W.R. negative in blood; C.-S. F. normal.

S. was given mercury and potassium iodide by mouth and courses of intravenous injections of novarsenobillon. C.-S. F. was completely normal when next examined, three months later, and has remained so. Positive W.R. in the blood persisted for 10 months, after which it remained negative. D., the patient who first came under observation, died in May, 1923.

## *Commentary.*

There are several points of interest in this family record. The previous histories of the parents gave no indication of syphilitic infection, and the father denied having had a primary sore. It is difficult to imagine that the three children suffering from neuro-syphilis had unrecognised primary infections in childhood, so, in spite of the absence of any evidence of syphilis in the parents, it may reasonably be assumed that the disease was in each case inherited. Although there still appears in some text-books the assertion that an ovum may be infected by a spirochæte conveyed in a spermatozoon and so give rise to a syphilitic fœtus, it is practically certain that inherited syphilis is always an infection conveyed by the mother to the fœtus. In the case under consideration it is probable that the mother was infected by the father, and that their resistance or relative immunity prevented any clinical manifestations arising from the infection, though when this was conveyed to the children neuro-syphilis developed. The development of the disease in each case in the central nervous system may be an illustration of the preference for the nervous system which has been thought to indicate a special strain of spirochæte, but another possible explanation is that the nervous systems of the infected children were less resistant to disease than those of their parents. In this connexion it is interesting to note some evidence of inherent instability of the nervous system in the family of the mother, five of whom—father, two uncles, and two brothers—died in mental hospitals. There is lacking also that attenuation of virulence so often observed in the results of pregnancy in a syphilitic woman; the infection occurred only in alternate children, the second, fourth, and sixth having apparently escaped.

The result of treatment of the patient S. is not without interest. He certainly had some form of neuro-syphilis in its earliest stage—before the onset of symptoms or the presence of physical signs—and if left untreated he might have proved to be a case of dementia paralytica. So far, treatment has been successful in that the serological tests have remained negative for over two years. This record emphasises the importance of making a complete clinical and serological examination of the brothers and sisters of a patient found to be suffering from inherited syphilis.

I am indebted to Dr. George Riddoch for permission to publish these cases, and to Dr. P. Spark for notes confirming the diagnosis in the case of the patient A. X.

THE name of Mr. Townley Clarkson's collaborator in the article on Gonorrhœa in the Male, which appeared in THE LANCET of Jan. 10th, p. 110, should read W. J. Dwyer, M.R.C.S. Eng., Clinical Assistant, Venereal Diseases Department, London Hospital.

# Medical Societies.

## INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS.

A meeting of this Association was held on Jan. 15th at 28, Bedford-square, W.C., with Mr. G. H. Hamilton in the chair, when Mr. Somerville Hastings opened a discussion on the

### Nationalisation of Hospitals.

He admitted frankly at the start the enormous service which the voluntary hospitals had rendered, not only to diseased humanity, but to medical science in general. Besides cultivating the spirit of help and hospitality they taught one most valuable lesson—that of coöperation in the treatment of disease. A patient in a large voluntary hospital had at his service not only physicians, surgeons, and specialists in all kinds of disease, but also those skilled in treatment by X ray, radium, light, and other special branches of curative medicine, as well as registrars, pathologists, and chemists. The success of hospital treatment was largely due to the scientific team-work of all these members.

Now the chief criticism of the voluntary system to-day was that this cooperation hardly extended outside the four walls of any one hospital. Each hospital is a law unto itself, and the public health suffered because the hospital worked as an isolated unit and did not keep touch with other hospitals and medical institutions in its neighbourhood. One hospital would have a long waiting-list while another near by had half its beds empty. They kept little touch also with the general practitioner, who at present sent patients to hospital without a very accurate history and received them on discharge without a detailed record of their progress and treatment. It would be much better if the patient's doctor could remain in touch with him while he was in hospital, and still better if he could take some share in his treatment. Another disadvantage of the present system was that public-spirited men and women had to dissipate so much of their valuable energy in inventing fresh schemes for collecting halfpence.

### *Shortage of Beds.*

Nevertheless there were not too many hospitals, but too few. Hardly anyone realised how urgently the country needed more beds at the present time. The recent recommendation of the Voluntary Hospitals Commission for an increase of 10,000 beds greatly under-estimated the shortage. The necessary average was generally recognised to be 2½ beds per 1000 population; this meant 95,000 beds for our 38,000,000. Since, excluding the Poor-law infirmaries, the number available was only 50,500, the beds required were 44,500. The reason why the waiting-lists did not show this number was that doctors only sent their very urgent cases, as the others had little chance of entering within a reasonable period. For many reasons this demand was likely to increase in the near future. The health of town dwellers was inferior to that of country dwellers, and more and more of these were drifting to the towns. The increase of unemployment and the lowering of the standard of living was also making for more ill-health, and the housing shortage would make it more and more difficult for people who were seriously ill to be treated at home. Meanwhile the increasing complexity of medical science rendered institutional treatment indispensable for many patients if the best were to be done for them. The general public was becoming more interested in its health and less inclined to look on sickness as an act of God.

### *Decline of the Voluntary System.*

The voluntary system had depended in the past on three things—voluntary subscriptions, voluntary medical service, and voluntary management. The last few years, however, the voluntary hospitals had been receiving an increasing proportion of their revenue from public funds. According to the late Sir Napier Burnett, the voluntary hospitals of England and Wales, excluding London, received in 1920 14·36 per cent. of their ordinary income from public authorities. Now that patients were paid for from public funds doctors who gave their help freely in the past were beginning to demand remuneration, and rightly, because the admission of middle-class paying patients was robbing them of much of their private practice. Voluntary management alone remained. Since the war the whole voluntary system had been in the melting-pot, and its history was a record of frantic attempts to save the sinking ship. Enormous lottery schemes, contributory schemes, payments by in- and out-patients, and grants from the Exchequer had been employed, and now the Voluntary Hospitals Commission were recommending a grant of two million pounds to equip more beds. This was not in itself objectionable if the hospitals used it to give help to all those in real need (which they did not always do at present), but if public funds were used the public must be represented both on the allocating committee and on the bodies that used the money. Voluntary levies from the employees in various factories did not benefit only those who subscribed, and a tax that fell on everyone in the district, well or sick, would be much fairer. Also, what with compulsory insurance, friendly societies, trades-unions, and the like, the wage-earner's income was in danger of being so reduced as to make a proper standard of life impossible, and he was therefore more likely to become a patient than he was before. Patients' payments were even more objectionable, as the very poor hated to admit that they could not pay and the better-off classes felt that if they paid what was asked, however nominal the sum, they were not accepting charity. The real pauper class for whom the hospitals were founded were thus being excluded, and it was among these that disease took the firmest hold and acquired fresh virulence to attack others.

### *Future of the Hospitals.*

What was required to-day was a completely organised medical system throughout the whole country to give the best possible service free to everyone who wished it, and in each locality the hospital must be the centre of this scheme. Villages would have receiving centres with two or three beds; small towns would have local or cottage hospitals, and cases requiring special treatment would go to the county hospitals in large town or cities. National hospitals where medical students could be trained and exceptionally difficult cases treated were needed in London, Edinburgh, and other University centres. Each hospital would be the health centre of the district it served and be in constant and close cooperation with every other. There were already at Barry, Widnes, and Bradford hospitals controlled, supported, and administered by the local health authorities. Since these authorities were responsible for dealing with tuberculosis, venereal disease, and the treatment of school-children, it was essential that they should be able to control a certain number of beds. This change could only come gradually. First the Poor-law infirmaries should be taken over and run as first-class free hospitals with full visiting staffs, independently of the Poor-law. The voluntary hospitals should have the option of: (1) being taken over by the health authority; (2) remaining as they are; or (3) accepting a certain amount of subsidy with proportionate public representation. The deficiency of beds that would still remain could be made up by fresh building and by extensions. Country mansions that came on the market could be turned into convalescent homes to relieve the stress on the hospitals.

The mass of people were not content with things as they are, and no part of the Labour Party's programme received more applause than their hospital policy. The development of a National Hospital scheme was inevitable within 10 or 20 years, and his audience had two courses open to them. One was to resist this movement and have to submit to a hurriedly conceived inadequate system like that of the National Health Insurance Act; the other was to direct and educate the popular will so that the new order when it came would retain all the best features of the present voluntary system.

### *Discussion.*

Mr. R. H. P. ORDE (British Red Cross and Order of St. John) denied that the voluntary system had failed to "deliver the goods." It had proved its worth in the war, and if the hospitals were given the money they would continue to provide the admirable service they always had. Also, without the slightest intention of reflecting on the Bradford Hospital, it was obvious that even with unlimited funds at its back it could not compare with any of our voluntary hospitals. The hospitals might have been founded for the poorest classes, but except for the "middle class" the patients treated there came from precisely the same social ranks as they did a hundred years ago. The argument against the voluntary system that its hospitals had relied to a large extent on public funds was so ungrateful as to be incredible. These grants were payment for special work done; surely the hospitals had every right to them.

Mr. G. P. BLIZARD (Secretary, Public Health Advisory Committee of the Labour Party) said that he yielded to no one in admiration for the work that the voluntary hospitals had done for the country. Hospitals had been performing State functions all down the ages. No price was too high to pay for the treatment of disease, and hospital administrators should, like the Labour Party, think boldly of the net cost of their enterprises rather than of their actual outlay. The axiom "Penny wise, pound foolish" was truer in this branch of life than in most others. Nevertheless hospitals needed more coördination, as was shown by Sir Napier Burnett's illustration of three hospitals within a few miles of one another, one of which had empty beds, while the other two were overcrowded. Sir Napier Burnett had proposed to smash the hospitals into line, but the speaker wished to persuade them into line. It was a calamity that so many people should be unable to enter hospital. Treatment was much better in institutions, and a system of graded institutions should make it possible to treat all those people who were turned away through lack of coördination. The nation's requirement of beds, according to the finding of his Committee, was from 2–5 beds per 1000, and this brought the figure higher than Mr. Hastings's estimate. The deficiency was nearer 102,000 than 45,000, and the estimated cost £53,000,000. This would not come from voluntary subscriptions nor from contributions. Something far more radical must be done about the hospital shortage. The view of Labour was that it was bad for people to be so wealthy that they could afford to give large sums to hospitals, and that no self-respecting nation would let its hospitals depend on gambling lotteries and flag days. The distribution of wealth was at fault. All forms of contributory maintenance, like the compulsory health insurance, were in the nature of regressive taxation and fell most heavily on those who benefited least. The money for the hospitals should come from those who were suffering from being too wealthy. Cottage hospitals could be adapted from existing cottages or pairs of cottages in the same way as cottage baths had been in the North of England. The change would come more quickly than the 15 or 20 years Mr. Hastings gave it. The working of the Insurance Act had disclosed facts about ill health that were irresistibly compelling the country to accept State control of all hospitals. The question was not now "Can we afford it?" but "Dare we not afford it?"

Mr. E. W. MORRIS (House Governor, London Hospital) admitted that hospitals were crowded too closely together and unsystematically distributed. This was because they had originally been founded for sentimental rather than practical reasons. While admitting the faults of the present system, however, he said there were other ways of correcting them than handing them over to the Government to manage. Everything the State had done for the poor since 1601, when the Poor-laws were introduced, it had done without sympathy. The Government's heartless handling of tuberculous patients was a good example; governments were too heavy-handed and inelastic to deal with such a personal thing as sickness. They could give valuable help to research, but an office stool was not the place from which to treat a sick child. A great advantage of the voluntary system was its elasticity, and in times of epidemic a hospital could throw open all its beds to patients of that particular disease without filling up forms and waiting for Government approval. Still more valuable than this, however, was the guest-house spirit of the voluntary hospital, which the infirmary did not possess. The first sign of improvement in the reorganised infirmaries was their adopting the name "hospital," but they needed the hospital spirit as well. He did not see why a health authority should be entitled to representation in return for grants of money; it was simply paying for service rendered. With all the faults of the voluntary system one day's voluntary treatment was better than a thousand years in the infirmary.

Mr. H. E. JENNINGS (Secretary, Chelsea Hospital for Women) said that if hospitals and general practitioners had to make compulsory reports to one another it would come very hard on both sides. Nowadays any questions that one asked the other were answered. The country, it was true, needed beds, but we were told that we were on our financial beam-ends and needed every penny we could spare for our industries; to impoverish the country was simply to create a demand for more beds still. Nationalisation would not only be very expensive, but would destroy the voluntary spirit, and the public should be told what they might expect if it were introduced.

Dr. ETHEL BENTHAM (Labour Party Executive and Margaret McDonald Hospital) complained that the voluntary system did not provide funds enough for the necessary accommodation, and that it was impossible to get a patient into hospital except an urgent or operation case. Half of these unsuccessful patients refused to go into the infirmary and had to be treated, for the most part quite unsuitably, at home. The infirmaries, although greatly improved, still left much to be desired. The whole Poor-law system must be revised. The voluntary system had done good work and been a necessary phase of advancing civilisation, but it could not finance a real preventive service such as we needed.

Mr. J. MCKAY (Hospital for Sick Children, Great Ormond-street) feared that Government control would ruin the hospitals as it had the telephone system. If the voluntary system were given the funds it could meet all demands, and Government control was not the cheapest way to get the results desired. The present system needed coördinating by a more efficient medical service, and he saw signs of a revolution in the health services of London which would lead to the desired reforms. When the Poor-law came into the melting-pot the Insurance Acts should go too; they worked very unfairly on the voluntary hospitals, who treated gratis many patients who paid health insurance. Hospitals had every right to recover this expenditure from the health authorities, who had plenty of money.

Mr. W. H. REED (Hospital Saturday Fund) said that the worker contributed to the voluntary hospitals with a willing heart. The patient of the State-controlled infirmary was charged more than he would be in hospital and was pressed till he paid; he was paying a poor-rate already and was taxed heavily for his treatment as well. The voluntary system came out of the war impoverished by the work it did; a grateful public had wiped out that debt and would do this one.

Mr. HASTINGS, in replying to the points raised in the discussion, said he did not blame the hospitals for accepting public funds. He was pleased, for this was the thin end of the wedge. Also nationalisation was not evil in itself. We had tried to fight the war without it, and economic necessity had compelled us to nationalise one service after another. It was better that what money the nation had should be spent on hospitals instead of on mere luxuries, as so much was. The Poor-law and National Health Insurance were bad because they were framed only for one class; a really efficient service must be free and open to all. The measures against tuberculosis were bad because no government had spent enough money; the State handling of venereal disease and maternity welfare was good. It would not be impossible to carry over into nationalisation the friendliness that distinguished the voluntary system, for there was no reason why the people of goodwill who had built up this spirit should withhold their services when the hospitals were administered by the State.

## SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.

AT a meeting of this Society held at 122, Harley-street, London, on Jan. 18th, with Dr. F. R. WALTERS, the newly-elected President, in the chair, a discussion on

### OCCUPATIONAL THERAPY

was opened by Dr. J. E. CHAPMAN, who said that it was first necessary to define "occupational therapy," as all kinds of things were included under that term at present. He would define it as work provided to enable the patient to recover his health more rapidly than would otherwise be probable and to return him to his ordinary conditions of life mentally and bodily sound. Other considerations were secondary. The first work of this kind was introduced at Frimley and consisted of carting stones and small works in the garden, &c., without any economic considerations, but this soon changed to useful employment, and now the problem was still further complicated by the idea of vocational therapy. Every disease had its own problems of occupational therapy and it was impossible to legislate generally.

### *In Pulmonary Tuberculosis.*

The psychological effect of occupational therapy, said Dr. Chapman, was much more important than the bodily effect. Patients were in institutions for long periods with nothing to do and were bound to be bored. The sanatorium had been described as "the breeding ground of loafers," but well-organised occupational therapy produced a contented community. At Woolley the patients did not work for their own benefit only; they received no money, but were made to feel that every ounce of energy they put into the work meant more cash to enable another man to be installed in the settlement. Physical benefit also accrued from occupational therapy; patients who had no exercise but walking, which usually meant a good deal of loafing, were liable to return to their homes soft. Very many of them broke down within a short period, and hence the idea arose of altering their occupation, usually to some country job, regardless of the fact that this would mean an inadequate income, so that soon they would drift back to their old work. Then arose the practice of training patients to some occupation suitable to their condition, but when they were turned out into the world they were almost always incapable of making good in it. Before they had always been employees drawing regular wages, but employers did not want them after discharge, and they had no notion of the commercial side of business and so failed alone. The speaker was sure that many of them broke down more because of the difficulties and worries of employment than from their home conditions. It was essential to arrange employment for them, as, for instance, in the "Spero" leather works where 23 men from the King George V. Sanatorium at Godalming were working; there had been no real breakdown since its inception. A certain Jewish institution had reduced its percentage of relapses from 50 to 15 by a well-organised and almost self-supporting workshop. Training must be arranged with the view of putting a man in some specific job in some specific place. A skilled trade like leather work was only suitable for about 5 per cent. of patients; for the 95 per cent. the "factory in the fields" at Leeds had offered what seemed a satisfactory solution. Here the men were employed on unskilled labour for as many hours a day as they were fit for, and the scheme was paying its way. Undoubtedly some form of unskilled work of the repetition order was best for the majority of tuberculous patients, and the sale of materials would always pay the wages of instructors and incidental expenses.

### *In Mental Disorder.*

Lieut.-Colonel J. R. LORD said that it was impossible to get far in occupational therapy before coming across psychology, and to learn psychology it was necessary to go outside the usual text-books. "No man is born into the world whose work is not born with him" was a remark of James Russell Lowell, but many were uncongenially employed and their energy ill-directed and unproductive. That regular and congenial employment was essential to health and happiness had long been admitted, but it was only recently that occupation had been recognised as a factor in the causation and treatment of disease and mental unhappiness. Applied psychology would solve many social problems, most of which were due to the damming back of the basal instincts. Many physical disabilities led to a handicapped mental state—i.e., one in which the outflow of the psycho-physical energy was curtailed by physical or minor mental disabilities or both. For the prescription of vocational therapy it was essential that the physician should have a thorough and complete knowledge of the patient physically, mentally, and psychologically, and the requirements of the occupation must be correlated with the individual. The effects of the work on the patient should be systematically observed and noted, particularly with reference to his weight, appetite, bowels, sleep, personal appearance, posture, gait, &c. It was important to see that the amount of sleep obtained was proportional to the amount of energy required for the occupation. Occupational therapy was a powerful instrument in giving new interests, directing the psychophysical energy into new directions and breaking up bad mental habits.

There was, said Colonel Lord, no fixed boundary line between mental handicapping and mental disorder. It was difficult to tell whether there were a real organic change or merely a long suspension of function, but only a certain amount of re-education was possible. The best methods were simple handicrafts, mainly automatic movements. The basis was to try to get the muscles and physiological side going and to base an orderly habit of thought on the orderly movements with which it was coördinated in health and from which it was originally derived. The best form was a simple handicraft such as picking, tearing, or fraying, with materials pleasing to the eye. The work might be carried on quite automatically and unconsciously at first, but the patient became more collected, and later should be occupied in the work with which he was most familiar and could do most easily; the mind should be encouraged to flow along the channels of least resistance.

Occupational therapy, aided by sympathy and suggestion, was something more than diversion; in the confused and mindless there was nothing to divert. Diversion was needed for depression, anxiety, and certain neuroses where some control and ordered thought were retained. Vocational therapy was often harmful in these cases, as it worried the patients more. Simple games, exercises, and occupation calling only for muscular effort only helped them to sleep and digest. True vocational therapy was suitable for all convalescent cases, and helped them towards self-confidence and a new strength. Often their old occupation was gone and they had to face a new world and conquer it as best they could.

The same principles applied in chronic cases, although the ultimate objective was different. They were taught to employ themselves because it encouraged orderly conduct and induced content, helped the patients to maintain self-respect and individuality, put a brake on their deterioration, and stimulated a more normal flow of ideas. All institutional patients who had a particular form of mental handicap were liable to develop bad mental habits and a sense of inferiority, to become irritable, suspicious, antagonistic and often anti-social, and to fall an easy prey to quack doctors and agitators. They must be taught to work independently and not be pulled along by others. The work must be a united effort on the part of the doctor and social worker, helped when needed by an industrial psychologist or some such organisation as the National Institute for Industrial Psychology, which concerned itself with the problem of how to make the most of the individual and his work. A patient would take more interest in his work if it were useful and remunerative. Occupational teaching was best carried out in well-planned, well-ventilated classrooms.

*Some Sanatorium Experiments.*

Dr. Jane Walker described the occupational therapy tried at the Nayland Sanatorium, confining herself to work done by patients while actually in the sanatorium. The first enterprise was lace-making, which faded away after some years of success. French gardening was more and more modified until it became simple English gardening; it failed because it was unsuitable for the tuberculous; it was far too monotonous, and the "ring" was too close to allow of obtaining a market. They were now running a weekly lorry to town with farm produce very successfully, but this was done purely as a business project. Embroidery involved an expensive plant and the work was too intensive; patients were not interested in work when it took a day to do an inch. Dress making failed because one after the other had to give up the work and orders could not be carried out to time. Tailoring was even worse. Toy-making and boot-repairing were successful and were still carried out, but the latter did not pay its way. When the Government scheme for ex-Service tuberculous men was instituted, jewellery-making, furniture repairing, polishing, and watch and clock repairing were begun; these were still going on very successfully. They were now trying definite teaching of handicrafts, leather-work, simple stitching, &c., and, most recent of all, the making of bedroom slippers, which seemed to promise well. Handicraft met with much initial opposition but was becoming more popular. A first principle in employing tuberculous patients was that all possible situations about the sanatorium, such as maids, nurses, clerks, garden and poultry workers, should be filled by ex-patients, preferably from some other institution. Farm workers were best not drawn from ex-patients as the work was too heavy for them. No industry would pay if run entirely on tuberculous labour Occupational therapy we must have, and if we failed with one method some other must be tried if the sanatoriums were not to turn out lazy and unemployable people.

Dr. Esther Carling limited her remarks to the employment of ex-patients in institutions. This was the thing that seemed most valuable and worth while. Headway had been slow, and superintendents might help much by raising the question before their governing bodies. Twenty-eight out of 82 of her staff were ex-patients, and this represented the average they had maintained for some years. The quality of service was excellent. The disadvantages of breakdown and sick leave were obvious, but were insignificant beside the loyalty of these employees, a factor which few people outside recognised. No superintendents who had tried ex-patients ever went back on their choice, for they discovered its great psychic value. It was better than any kind of handicraft. Nevertheless, a combined effect was necessary to establish the principle firmly.

Dr. J. Watt attested the therapeutic value of work, not only in all kinds of ailments, especially the neuroses, but also to healthy people. A gospel of work preached by some eminent publicist would cure many social ills.

Colonel Lord mentioned the part played by the education officers and psychologists of an institution for neurotic soldiers in allotting men to therapeutic work suitable to them, and giving warning when an occupation was unsuitable for a certain patient.

Dr. Vere Pearson stressed the value of walking, and said that occupation should not be allowed to exclude it. Sport was not only a valuable form of exercise but helped to prevent and cure tuberculosis. He had encouraged some of his patients to play on a putting green as an exercise.

The President gave warning against putting patients to work too early, and stirring up mischief in the chest and the "gambling spirit." Occupation was useful for patients still in bed with slight feverishness.

Dr. F. J. C. Blackmore pleaded for more coöperation between superintendent and tuberculosis officers, and for caution in founding new workshops.

Dr. Niven Robertson mentioned the frequent breakdowns, and Dr. W. Goodchild the low morbidity of ex-patients employed on institution staffs.

Dr. W. C. Fowler advised that the patient should be told the definite time he was likely to be kept in bed. When he knew this he used his time; when he did not he was inclined to loaf.

Dr. H. O. Blanford said that one of the chief obstacles to the employment of ex-patients was the opposition of the healthy employees.

Dr. J. D. Stevens deprecated the misinterpretation of the clinical conception of graduated work by practitioners, who graduated to hold the patient's condition stationary and not to improve it.

Dr. Jane Walker agreed with Dr. Carling's experience of the value of staffing sanatoriums with ex-patients: 120 of her staff out of 150 were ex-patients. Their employment outside institutions, however, was an insoluble problem.

# Reviews and Notices of Books.

## Carbon Monoxide Poisoning.

*L'Oxyde de Carbone et l'Intoxication Oxycarbonique.* By Maurice Nicloux, Professeur à la Faculté de Médecine de Strasbourg; Membre correspondant de l'Académie de Médecine. *Paris*: Masson et Cie. 1925. Pp. 256. Fr.22.

Dr. M. Nicloux may be congratulated on an excellent monograph. He states that he has been working on CO poisoning for many years and internal evidence indicates that he is a master of his subject. After the natural, technical, and laboratory sources of carbon monoxide have been reviewed, the chemical and physical properties of the gas are discussed and also its compound with hæmoglobin. The behaviour of hæmoglobin in known mixtures of oxygen and carbon monoxide under a variety of conditions and at varying temperatures is studied, and Dr. Nicloux shows experimentally that hæmoglobin in its combination with oxygen and carbon monoxide obeys the law of mass action. A large number of experiments are given on animals under varying conditions to correlate the percentage saturation of the blood with carbon monoxide and toxic symptoms, the author stressing the importance of what he calls the coefficient of poisoning, that is, the ratio between the percentage by volume of carbon monoxide in the blood and the percentage of carbon monoxide when the same blood is fully saturated. Treatment also receives attention. Some 70 pages at the end of the book are devoted to technique of the estimation of carbon monoxide and oxygen in blood and air, and the author critically surveys the various methods employed in such analyses, describing valuable apparatus of his own design.

Altogether an admirable little book.

## PÆDIATRICS.

*The Call of the Child.* By A. Dingwall-Fordyce, M.D., F.R.C.P. Edin., Physician, Royal Liverpool Children's Hospital. London: A. and C. Black. 1926. Pp. 83. 2*s.* 6*d.*

This little book differs in some respects from the majority of those which have appeared on the same subject, and serves to exemplify the great variety of standpoints from which the study of child welfare may be approached. Its virtue lies in its clear presentation of the essentials upon which all schemes of management and treatment of children should be based. Questions such as infant feeding, dietetics, and exercise, on which so much has been written, are discussed succinctly and with a view to simplification. The most original part of the book is that devoted to the problems of the management of the ailing or crippled child, containing many suggestions of great practical use. A book of this kind is of particular value when it carries the authority of so experienced a pædiatrist; it may be recommended as confidently to parents and workers in institutions as to the medical profession.

*Clinical Study and Treatment of Sick Children.* Fourth edition. By John Thomson, M.D., F.R.C.P. Edin., Consulting Physician to the Royal Edinburgh Hospital for Sick Children. London and Edinburgh: Oliver and Boyd. 1925. Pp. 912. 30*s.*

Dr. Thomson has achieved notable success in the revision of his well-known text-book. The fourth edition has received numerous additions which have decidedly increased its completeness, while the style and arrangement of the book, which have rendered the previous editions so attractive, have undergone little change. A few sections have been added which are entirely new; these include descriptions of the exudative diathesis, erythrœdema, and the care of deaf, blind, and crippled children. The greater part of the new material has been incorporated in the text of the previous edition. The author's presentation of the disorders of the nervous system has hitherto been a notable feature of this work, and a large number of the new additions refer to them. The sections on encephalitis, cretinism, mental defect, and spastic paraplegia have been rewritten, and those on many other nervous disorders enlarged. We note that Dr. Thomson adheres strongly to the view, which has frequently been assailed of late, that the majority of spastic diplegias are natal, not prenatal, in origin. New work has been included in the accounts of pneumococcal peritonitis, rickets, and congenital syphilis, to mention a few only. The doctrines of Czerny and Finkelstein will still render the chapter on food disorders somewhat formidable to the student, but the nomenclature has been to some extent simplified. This work has gained considerably in comprehensiveness, and is thoroughly up to date; it is now of a size which makes it equally useful as a text-book and as a book of reference.

*Feeding and the Nutritional Disorders in Infancy and Childhood.* Fourth edition. By Julius H. Hess, M.D. Philadelphia: F. A. Davis Company. 1925. Pp. 556. $4.50.

This book by Hess is already widely known in America and in this country. In the three years that have elapsed since the last edition was published a good deal of work has been done on the principles underlying the artificial feeding of infants both in health and disease, and especially on the quantities needed of the individual food elements. This newer work is incorporated in the present edition, and some excellent diet sheets for children from 6 months to 6 years of age have been added. The author allows more cereals than is customary in this country—the giving of cereal waters to artificially-fed infants from 1 month of age, and cereal flours from the third month, is recommended—but in the section on rickets the danger of excess of starchy foods is duly pointed out. Nutritional disorders, the classification of which is on the newest lines, are fully and lucidly dealt with in eight chapters, one entirely new chapter on cœliac disease being incorporated in this section. This is probably the most valuable and the most original part of the book. Other sections, dealing with rickets, spasmophilia, scurvy, acidosis, and the anæmias of infancy, are equally authoritative. The volume is well illustrated and may be warmly commended to the medical practitioner as dealing in a common-sense way with the ætiology and treatment of the nutritional disorders of childhood.

*Simplifying Motherhood.* By F. H. Richardson, M.D. New York: G. P. Putnam's Sons. 1925. Pp. 263. 7*s.* 6*d.*

The author of this book has propounded a scheme of infant feeding and management based upon a number of hypotheses which in a large measure run counter to commonly accepted ideas on the subject. His enthusiasm for breast feeding will meet with general accord, but he may justly be suspected of overstating his case, and it is doubtful whether the cause which he advocates is well served by his estimation of the relative chances of breast- and bottle-fed babies at 80 and 20 per cent., or by the extremely disparaging account which he gives of almost every method of artificial feeding. Briefly summarised, Dr. Richardson's contentions are as follows: Every woman can nurse her child; it is impossible to overfeed a baby fed at an interval of three or four hours; the correct estimate of the sufficiency of the breast milk is obtained, not by the test feed, but by giving a complementary feed and allowing the infant to satisfy itself, this procedure being accompanied by manual expression of any remaining breast milk. The child is allowed to feed for as long as it will, even beyond the hour; is fed twice in the night, whenever it happens to wake, until the habit of sleeping through the night is acquired spontaneously. It is emphasised that this routine must be supervised throughout by a physician. The author recognises that his views will not meet with general acceptance, and he appeals to medical practitioners to give his method a trial. Probably the majority of them will prefer to do this before placing this book in the hands of parents.

A Text-book of Pharmaceutical Chemistry. By Arthur Owen Bentley, Ph.C., Director of the Department of Pharmacy, University College, Nottingham; and John Edmund Driver, M.Sc., A.I.C., Lecturer in Chemistry, University College, Nottingham. London: Oxford University Press. 1925. Pp. 456. 18*s.*

This book has been written to meet the needs of those studying for the Pharmaceutical Society's diplomas and for degrees in pharmacy. It is divided into two parts devoted respectively to inorganic and organic chemistry. The first part is concerned almost exclusively with the inorganic substances of the British Pharmacopœia, while in the second part, which claims to give a systematic account of organic chemistry, particular emphasis is laid upon substances included in the Pharmacopœia. The introduction states the intention that the reading of the book should be accompanied by a study of the corresponding portions of the Pharmacopœia. Parts of the volume, indeed, consist of transcripts of the Pharmacopœia, and in other parts it merely amplifies and explains those portions of the Pharmacopœia which appear to require such treatment. The scrupulous following of the Pharmacopœia has resulted in a somewhat superficial treatment of many branches of the subject—for example, the chapter on carbohydrates gives but an inadequate idea of the chemistry of this highly important group of substances. The book may be useful to students of pharmaceutics.

THE LANCET.

*LONDON: SATURDAY, JANUARY 23, 1926.*

## TRANSFUSION OF BLOOD.

THE establishment of blood transfusion as a therapeutic measure in civil practice in this country dates only from the beginning of 1919, when war conditions were relaxed and those who had learnt the technique of transfusion were returning to their practices. During those seven years many thousand transfusions have been performed for a variety of conditions, and there is no reason for doubting that the results have given general satisfaction. It must be admitted, however, that on the medical side transfusion has definite limitations. Probably the great majority of medical transfusions have been done for pernicious anæmia, a disease which is never cured by this treatment though it may be held at bay for varying periods up to several years. The necessity for repeated transfusions is in itself confession of partial failure. The second prime indication for transfusion is hæmorrhage from a gastric or duodenal ulcer. The dictum that "patients never die as a result of hæmorrhage from a bleeding ulcer" may still gain some credence, but is gradually giving way before *post-mortem* room evidence. The fallacy of supposing that transfusion will encourage hæmorrhage by causing too great a rise in blood pressure is also losing ground. Transfusion has, in fact, proved its claim to be regarded as almost a routine measure in hæmorrhage from acute and chronic ulcers. In the first group it is more likely to assist in stopping bleeding than to encourage it, and accelerates the patient's recovery; in the second it tides the patient over a grave crisis and makes possible the performance of the necessary operation. Transfusion is also of proved value in surgery in combating the shock caused by any severe operation, such as partial gastrectomy or disarticulation of the thigh at the hip-joint, though it has become less often employed in the first of these examples as improved methods of anæsthesia have come into use. Another group of patients who may be definitely benefited by transfusion includes those suffering from chronic intoxication by pyogenic or other micro-organisms. The results of its use as a specific agent in these cases or in septicæmia by means of the principle of "immuno-transfusion" introduced by Sir ALMROTH WRIGHT and his co-workers in 1923, does not seem quite to have fulfilled the hopes based upon the laboratory work which suggested it; but the general effects of an ordinary transfusion have certainly been good. Opinion concerning the other less frequent indications for transfusion, such as melæna *neonatorum*, hæmophilia, purpura hæmorrhagica, and pneumococcal peritonitis, has not undergone any striking alteration.

Transfusion has probably been more freely used in hospital practice than outside, owing to the presence in hospital of greater facilities for obtaining apparatus and blood donors, but with a little forethought and organisation these factors do not present any real difficulty in any circumstances. Knowledge of the possible dangers due to the incompatibility of certain "blood groups" has been widely diffused, and misadventures attributable to this cause have been almost unknown. Probably very few transfusions have been performed without the preliminary tests which are known to be necessary. Doubt has several times been cast upon the precise truth of the statement that human beings can be rigidly divided into four groups, but although laboratory evidence may have fostered this doubt, clinical results have always tended to dispel it. In the department of technique no very striking advances have been registered, though several modifications of existing methods have been brought forward. The present issue of THE LANCET contains two contributions bearing on this side of the problem, and these will be seen to be to some extent in opposition. In the United States, the home of transfusion and the scene of many original investigations of the problems connected with it, discussion has always centred upon the relative merits of the use of so-called "whole blood" and of citrated blood. The advocates of "whole blood" have maintained that the use of citrate is to be held responsible for the minor post transfusion reactions which have often been observed and that it should therefore be entirely abandoned. Advocates of citration have then demonstrated that the reaction follows in almost the same proportion of cases whichever method has been used.

The truth of the matter is difficult to seize, but the probability seems to be that the reactions are due to more than one obscure factor in technique and to peculiarities in individuals even in one blood group. The importance of the matter may easily be exaggerated, for the reactions are scarcely ever harmful, and some observers believe that the therapeutic result is better when a reaction has occurred. A statement that, in an occasional instance, a reaction has proved fatal is difficult to substantiate, for other possible explanations cannot be excluded, and general experience suggests that some other factor was probably responsible. The position, however, is arguable, and Dr. ROBERT PLATT, of Sheffield, now makes a plea for the routine use of defibrinated blood on the grounds that the technique is simple and that no reactions ever occur. He regards it as an established fact that the minor reactions are all due to citrate. Citrated blood has proved, however, to be, in some hands, so entirely satisfactory for general purposes that it will not be lightly abandoned in favour of another method. The citrate has also a somewhat paradoxical value as a hæmostatic agent when introduced into the circulation, and its continued use may be advocated on this ground alone. Our second contributor, Dr. H. H. MOLL, of Leeds, seeks to introduce a modification of the usual citrate apparatus, in which he uses a "Record" syringe fitted with a two-way tap. The same idea is incorporated in the apparatus used by Dr. PLATT. The point of difference lies in Dr. MOLL's attitude towards the use of citrate, for far from questioning the propriety of employing it, he adds to the blood more than twice as much citrate as is usually considered necessary. Clearly no general agreement upon the pros and cons of citrate for transfusion has yet been reached. Disagreement, however, is not likely to prove so fierce in this country as it has done in America, for specialisation has not yet resulted here in the evolution of the "transfusionist" whose sole interest lies in the practice of this specialty.

◆

## MEDICAL RESEARCH IN 1925.

EVERY year an attempt is made to describe in small compass, in fairly balanced proportion, and in terms intelligible to those without special technical knowledge, the multifarious research activities being subsidised by the Medical Research Council. And every year, as the scope of these activities widens, the task of summarising still further in our columns the highly condensed annual report of the Council becomes harder, if, indeed, a mere catalogue of names, places, and subjects is to be avoided. Such a catalogue in its proper place, which is the appendix to the report, certainly indicates the size of the net cast by the Council, and the curious treasures hauled in sometimes from unexpected sources. Here may be found, for example, a formidable list of investigation committees. Their terms of reference include Statistics, Biological Standards, Bacteriology, Problems of Child Life, Eclampsia, Vitamins, Nutrition, Dental Disease, Clinical Uses of Oxygen, Injuries of the Nervous System, Mental Disorders, Hæmoglobin, Tuberculosis, Salvarsan, Canine Distemper, Radiology, Biological Actions of Light, Chinchona Derivatives and Malaria, Physiological Actions of Alcohol, Anæsthetics, Pituitary Extract in Labour, Status Lymphaticus, Physiology of Vision, Legibility of Type, and Miners' Nystagmus. The existence of these committees depends for the most part on the gratuitous service of experts who are prepared to criticise without bias experimental, statistical, or clinical findings and to correlate, where possible, without attempting to control, individual enterprise. Some of the committees arise from the collaboration with the Council of other bodies such as the Pathological Society of Great Britain and Ireland, the "Field" Distemper Council, the Lister Institute, the British Empire Cancer Campaign, or a section of the Royal Society of Medicine. An index of persons working in close relation with the Council contains nearly 700 names. Ninety-one institutions in Great Britain and Ireland have supplied hospitality to subsidised workers or material for investigation, not including 28 Government departments or 35 other bodies, at home and abroad, who have coöperated in various ways.

It is clear, then, that no brief general survey of the research in hand could be adequate. However, in the year under review, as on former occasions, The Lancet has been selected as a vehicle whereby much of the important work accomplished has been conveyed to the profession, and we may assume our readers to be familiar with the advances recorded in our columns. It is a different and more subtle affair for the general medical reader to assess at its true value any new discovery or technical method. The introductory chapter to the report of the Council, dealing critically with progress made in the study of immunity and infectivity, with the standardisation of biological substances, and especially with filter passers in relation to cancer, will be welcomed. For the development that excited most interest in all civilised countries during the past year was the publication in The Lancet of July 18th, 1925, of the two complementary papers on this subject by W. E. Gye and J. E. Barnard. It is unusual in a community as properly sceptical as the British scientific world for a preliminary communication still without independent confirmation to create such an impression. The Medical Research Council supply the reason; that the evidence brought forward by Dr. Gye resolves what they describe as the great paradox of medicine. Malignant disease occurs in all animals. Clinically and biologically it is an individual disease, maintaining its own characters whatever the scene of its being. Experimentally, however, it has hitherto been found impossible to propagate tumours except by a transference of living cells, and even then only to the same species. Experimental study, therefore, indicated a particularity or specificity of malignant tumours, while clinical and general observation had seemed to establish a uniformity and generality. Those who reflected on the subject from the clinical point of view were inclined to believe that some common causative factor must exist to link up the tumours of man and of the other animals. Those who worked experimentally tended, on the whole, to reject such a belief. If, however, the conclusion, supported by experiment, that the common factor for all malignant disease is a filter-passing virus, harmless by itself, while another chemical factor, without which no cancer can occur, is specific and is derived from tumour cells, is accepted, the anomaly disappears. The explanation offered is so attractive and fits in so well with each of the conflicting arguments that even as a theory it would have received attention; but here is no unsupported theory. Mr. Barnard had set himself the task of devising special means for demonstrating the presence of a very small organism by ultra-violet light. The success of this work and of other developments of optical technique allowed the presence or absence in given preparations of the virus, as demonstrated experimentally by Dr. Gye, to be detected independently. Thus each part of the work could provide a check on the results of the other. The possibility of this cross-checking of the results gained on either side and its uniform success greatly increased public confidence in the results obtained.

The repetition and extension of the work in this and other countries is the next step. Coöperation with the staff of the Imperial Cancer Research Fund at the Stroud laboratory, which adjoins the Council's farm laboratories at Mill Hill, is already established, and will be facilitated by the proposed transfer of Mr. Barnard's department of applied optics from Hampstead to new buildings at Mill Hill. The sum of £10,000 in instalments of £2000 a year, allocated to the Council by the trustees of the late Sir W. Dunn, is being used for this purpose. Even at this stage the Council record their belief that "this new work transforms our outlook on the general problem of the causation of cancer."

◆

## CARBON MONOXIDE POISONING.

Few substances have created such a wide interest in biology as carbon monoxide gas. It is of interest to the physiologist, to the pathologist and toxicologist, to the physician, to those concerned primarily with the welfare of individuals engaged in industrial and mining occupations, and to those responsible for the health of the general public. In a recent lecture[1] on the absorption and elimination of volatile substances through the lungs, Prof. Yandell Henderson speaks of certain aspects of CO poisoning as it now affects the lives of all civilised men. He deals especially with the potential impairment of health and efficiency which may result from the pollution of the atmosphere with small amounts of CO such as may be contributed by the exhaust gases of petrol engines in congested regions of traffic. It has been found in New York City that concentrations of 1 part CO in 10,000 parts air are rather common, and from experiments on the rate of absorption of this gas by the blood of individuals exposed to varying concentrations of CO in air, it has been concluded that breathing in such an atmosphere for periods of several hours will lead to a percentage saturation with CO of an intensity sufficient to bring about slight symptoms of oxygen want. In garages and assembling and repair shops the conditions are increasingly bad, and the workers suffer from asphyxial headaches and lack of mental control; whilst only last week Dr. A. G. G. THOMPSON drew attention in our columns[2] to unpleasant symptoms of similar origin which he has observed amongst engine-room workers on motor-driven ships. Drowsiness, headaches, vomiting, loss of appetite, and a yellow discoloration of the skin are amongst the results of engine-room life under the new motor régime, and this debility amongst men employed in motor works—whether ashore or afloat—obviously demands careful consideration.

---

[1] Brit. Med. Jour., Jan. 9th, 1926, p. 41.

The number of recent fatalities in garages has made it unnecessary, perhaps, to speak of the dangers of exhaust fumes as an acute poison, though the public is clearly still ignorant of the dangers of the closed garage door. The rich mixture of petrol and air used in starting a car is particularly noxious because the fuel does not undergo complete combustion. Prof. HENDERSON points out that the maximum efficiency of the petrol motor is attained when the ratio of air to petrol (by weight) in the gas mixture is about 15 to 1. Under these conditions complete combustion occurs. Unfortunately, it is with richer mixtures that the maximum power is obtained, and with carburettors adjusted to deliver 12 lb. of air to 1 lb. of petrol this further power output is only obtained at the expense of 6 per cent. CO in the exhaust gases. In Great Britain, owing to the tax imposed being made directly proportional to the rated horse-power of the engine, less highly powered cars are employed and hence the factors making for serious atmospheric pollution are considerably less potent than in the United States. The question will naturally be asked: What evidence is there that the extremely small contamination of the atmosphere with CO such as may occur in congested traffic areas can bring about any prolonged or permanent impairment in the efficiency of people exposed to it? Before attempting to answer this question we must inquire more fully into the nature of CO poisoning. CLAUDE BERNARD was the first to suggest that the cause of death in CO poisoning was anoxæmia, and though for many years the idea was prevalent that the gas had other specific toxic effects on the tissues, J. S. HALDANE demonstrated conclusively by experiments on mice that CLAUDE BERNARD's contention was the correct one. The gas is not destroyed in the body; it can be recovered quantitatively from the expired air; and the well-known symptomatology of CO poisoning is due simply to the functional destruction of hæmoglobin for which the gas possesses a high affinity. The symptoms are similar to those of anoxæmia such as is found in mountain sickness. But whereas in the latter condition respiratory distress is a most prominent feature, in the anoxæmia of CO poisoning it seems to be the higher cerebral centres which are primarily affected, fainting being extremely common. This difference, as HALDANE points out, is due to the fact that the respiratory centre responds to changes in the *pressure* of oxygen in the arterial blood, and in even severe degrees of CO anoxæmia this may be normal.

The question may now be pertinently put that if in CO anoxæmia the oxygen pressure is normal but the functional hæmoglobin diminished in amount, why do not patients with degrees of anæmia far more severe than the functional anæmia resulting from CO poisoning suffer correspondingly acute cerebral symptoms of oxygen lack? The answer to this question follows from a consideration of the effect of CO on the dissociation curve of oxyhæmoglobin. The curve, as was shown by J. B. S. HALDANE, is shifted to the left, so that a given amount of oxygen can only be obtained under these circumstances by the tissues at a mean oxygen pressure considerably below that obtaining in cases of simple anæmia with the normal dissociation curve. It seems that in order to work efficiently the higher cerebral centres must be presented with a large supply of high pressure oxygen, and possibly the headache of anoxæmia is due to a protective capillary dilatation with extravasation of fluid from the blood to the tissues. There is, in point of fact, some evidence that this occurs in carbon monoxide poisoning. Our ignorance of the reactions of the cerebral capillaries, however, is profound; but it may tentatively be suggested that cerebral capillary dilatation and œdema occur in varying degree in conditions of anoxæmia, and that the petechial hæmorrhages which MOTT has described in the nervous system of those having died from CO poisoning are the extreme and pathological result of this call for oxygen by the master tissue of the body. In this connexion we must bear in mind the central and peripheral nervous symptoms—impaired cerebral control, disturbances of vision, peripheral neuritis—which frequently follow severe CO poisoning, and even mild poisoning if it be frequently repeated.

## A CASE FOR CLEMENCY.

AT the quarterly meeting of the Council of the Royal College of Surgeons of England held on Jan. 11th a further application from Dr. F. W. AXHAM, for restoration of his Membership, was considered, but the Council did not see fit to rescind the resolution of July 13th, 1911, removing Dr. AXHAM from being a Member of the College. This meeting had before it a letter from Dr. AXHAM, stating that he fully appreciated the necessity for members of the profession to abide by the rules of its governing body and for those who find themselves in any circumstances unable to do so to accept the consequences. Dr. AXHAM went on to submit that he has now been more than sufficiently penalised, and to beg the Council as an act of grace to restore his name in the Membership roll of the College. The Council of the Royal College of Surgeons of England have finally declined to do this, and the decision has not been lightly taken, for great pressure has been put on the Council from many sides to reconsider their decision, and it has only been the conviction that in this matter they were the trustees of public safety that has determined their course. The application for restoration of Dr. AXHAM's licence came before the Royal College of Physicians of Edinburgh on Jan. 10th, when by a resolution of the majority Dr. AXHAM's appeal was granted. Lord DAWSON has already voiced the feeling of a considerable section of the medical profession that favourable consideration "as an act of grace" should be given to Dr. AXHAM's reinstatement on the Register. The present position will not, we think, be construed as a change of policy in regard to the covering of unqualified practice, but rather as following the principle laid down in a memorandum, just issued by the Registrar of the General Medical Council, that, should a practitioner's name be erased from the Register, it may, after a lapse of time, be restored thereto, if that can be done with safety to the public. Presumably the legal difficulties to replacing Dr. AXHAM's name on the statutory roll have been removed.

# Annotations.

"Ne quid nimis."

## DRUNK OR SOBER?

WITH the advent of the motor-car the problem of deciding in a given case whether a driver is drunk or sober has assumed an importance even greater than before. For the "one-'hoss shay" has been supplanted by the 20 or 40 h.p. engine, and the mentality of the horse, which by instinct avoids dangers and by training respects the footpath, no longer provides a buffer between the drunken driver and the innocent wayfarer on his route. In the days of horse traffic there was always at least one sober animal of the party. The drunken motorist, however, has no such assistance; he is a source of untold danger to all around him, and must be dealt with severely when guilty. It is in connexion with this subject that the paper read at the meeting of the Medico-Legal Society last Tuesday evening and reported on p. 207, is of especial importance. It records a practical attempt by Dr. G. Carter and Dr. H. W. Southgate, of Sheffield, to obtain definite data upon which the question of "drunk or sober" can be settled. Dr. Southgate shows, as the result of a series of experiments, that the curve of alcohol-concentration in the blood, after the administration of a known quantity of alcohol, is remarkably definite and constant in all cases. The curve of alcohol in the urine shows similar characters at a different percentage, so that, at any moment after the alcohol is taken, it is possible from an examination of the urine to make an approximately accurate estimate of the amount of alcohol in the blood at the same time. It is also possible within certain limits to say whether the alcohol-concentration is sufficient to cause drunkenness. Dr. Southgate's experiments are not only of interest from the physiological point of view, but they raise many problems which require investigation. The practical application of the method was dealt with by Dr. Carter, who reported a series of cases which had come under his notice as police surgeon, and gave particulars of some 25 cases, arrested for drunkenness, in whom the urine passed after arrest was thus examined for alcohol. So far the method has been tried in too few cases to warrant a final decision as to the extent of its value, but the results obtained are promising. It has at least a scientific basis and may prove a valuable help in this difficult problem. If it is to be really useful, the chronic hard drinker who can consume large quantities of spirits without change in demeanour would have to show a smaller alcohol concentration in blood and urine after dinner than that of the schoolboy who is excited and voluble after half a glass of port. Even now it might be of crucial assistance in certain cases. Thus a negative result would be an irrefragable proof of innocence, whilst one that was strongly positive would confirm the action of the police in making the arrest.

## THE NEED FOR SPECIAL HOSPITALS.

THE establishment of a new special hospital for the prevention and treatment of heart disease in children is noteworthy as showing the movement towards the specialisation of hospitals. At its opening Dr. I. Harris discussed at some length the position to-day in large cities like Liverpool. It has become necessary, he said, that particular types of cases should be in charge of people with special experience, and as a general principle this can hardly be gainsaid. But in a place like Liverpool the existing hospitals are not large enough to be split up into special units treating special diseases. In some cities a great many hospitals have been built, and this dissipation of effort has meant that few of these hospitals are large enough to undergo internal differentiation of function. In Manchester, for instance, as was recently pointed out by Mr. L. G. Brock, of the Ministry of Health, there are 14 in-patient institutions. The Royal Infirmary and the Barnes Convalescent Home contain 750 out of the total 2045 beds for the city, but six of the remaining 13 have 50 beds or less. There are two ear, nose and throat hospitals, with 24 and 11 beds respectively. Can such an arrangement really make for efficiency? As Dr. Harris pointed out, the only solution of the problem where so many institutions are in competition is to pool resources of bed, scientific apparatus, and medical staffs. Some coördinating organisation is an essential, and there is no doubt that such a body, with its bird's-eye view, would soon be convinced of the futility of a method by which every hospital tries to treat every disease. Reorganisation into specialist hospitals would be the inevitable sequel. From the medical point of view it is obvious that to bring all the nerve cases of Liverpool under one roof, instead of letting them remain scattered about the city in the care of physicians not specially interested in them, would be to increase the efficiency of their treatment. And not of their treatment only, for there would also be improved opportunity for teaching and research. From the economic point of view another advantage would be a unified appeal to the public for funds. This might not be welcome to those hospitals which are successful in the scramble to raise money, but Mr. Brock is certainly right in saying that the present multiplication of requests for alms is not only wearisome and distracting to the public but is against the complete success of any one institution.

There are good grounds, then, both medical and financial, for thinking that specialisation of hospital function is overdue, though any drastic or sudden alteration in the present arrangements would be regrettable, because continuity of tradition is really valuable. Collaboration, rather than unification, is the ideal, and it is an ideal that is making headway. So far as children's diseases are concerned there has long been in Liverpool a measure of what Dr. C. J. Macalister has called "the federation of hospital treatment." An organisation exists there whose function it is to ensure that children shall go from a central out-patient clearing house to the institution most suitable to their needs, and elsewhere the large general hospitals are already learning to shift their patients into annexes and convalescent homes as early as they can, and are beginning to regard themselves to a certain extent as in-patient clearing houses. The idea is sound as well as progressive, provided that the needs of the patient are never forgotten in the search for a symmetrical organisation. Specialisation amongst doctors has its disadvantages, and they are very real. But specialisation amongst hospitals has few essential dangers and its advantages are incalculable.

## LEAD AND ARSENIC IN TARTAR EMETIC.

A QUESTION of considerable interest is raised in our columns this week by Mr. E. Griffiths-Jones, chief chemist of the Public Health Laboratories at Cairo. How much lead and arsenic should be tolerated in tartar emetic? The harassed practitioner who naturally desires to know as definitely as possible what drugs he is administering will almost certainly say "none." According to Mr. Griffiths-Jones the manufacturers of tartarised antimony both in England and Germany appear to take a rather different view, which they base on the requirement of the British Pharmacopœia: "Yields no characteristic reactions for lead . . . [or] arsenic." The English firm say right out that all samples of the preparation examined by them contained about 0·1 per cent. of lead, whilst the German firm contend that their preparation does not contain lead and, further, that if it did, the B.P. tests would not detect it. This contention is not new. It has successfully been urged in the case of tartaric acid. The B.P. is a publication compiled under high medical authority and chemical advice. It cannot be admitted that the meaning of the requirement quoted above is that, when tested in a manner which cannot be expected to detect any but ridiculously large proportions of lead, no lead shall be found. It would surely be reasonable to suppose that "no characteristic reactions" means rather that the proportion of lead shall be so small that it cannot be detected by any recognised means. The amount of lead actually found by Mr. Griffiths Jones in one case exceeded 1 part in 1000 of the preparation. Taking the amount of tartarised antimony injected during a course of treatment for bilharzia as 25 gr. (1 6 g ) this would contain in such a case about 1/30 gr. of lead The amount is small, but its presence might cause and apparently has caused complications which are not normal effects of the administration of antimony. Having regard to the extensive use of tartar emetic in treating bilharzia in Egypt, it seems clear that no uncertainty as to its properties should be tolerated. Let lead be administered as one of its salts, if desired, not as an impurity of another drug

## TWENTY YEARS OF SANATORIUM WORK IN FRANCE.

Dr. Guinard has brought out an illustrated book[1] to sum up and so commemorate the results of over 20 years' work and experience at the three sanatoria (the author prefers the plural sanatoriums) of Despeaux-Rubod (1903), with 120 beds for men; Petit-Fontainebleau (1909), with 108 beds for women, and Fontenay (1913), with 152 beds also for women, grouped under the designation Bligny and situated in the Chevreuse Valley, 25 kilometres from Versailles and 40 from Paris The climate is pleasant and equable, and the surroundings ideal for the purpose The site, formerly occupied by an ancient château, has historical associations with England. The three sanatoria (for the middle- and working-classes) are all distinct and separate, not even in view of each other, for the medical director is strongly opposed to a "mixed" sanatorium, not because the tuberculous necessarily develop more than normally affectionate tendencies, but because the mingling of the sexes would introduce an element of disturbance into the calm and ordered routine of treatment, which would be always inconvenient and at times might become *dangerous*. In this spirit also the regulation is enforced that the exercise-period of the men is made to coincide with the rest hours of the women, and vice versa.

The architecture of the buildings and the allocation of services are entered into in great detail One noticeable point is that the balconies whereon the patients take their rest-cure are separate from, but in covered communication with, the cubicles and their 'lavabos" and facilities for personal toilette, into neither of which do the patients return until bedtime. The patients' day is spent between the balconies—*galeries de cure*—the large general room for reading, writing, conversation, and games, and the park and grounds with croquet, skittles, and other games Each patient spends on an average six hours in his or her rest-chair. The table appointments are met by coloured table-cloths to lessen the unsightliness of stains, separate serviettes and glasses, with racks for their reception in an annexe with toilet facilities The diet is generous and is based on the average of that required by a healthy individual plus one fifth The menus read temptingly, and perhaps descriptive food terms are more alluring in French than in English, but *saumon mayonnaise* would sound excellent in any language, and we can imagine few patients, whose caprices are the despair of every sanatorium cook, grumbling at a meal which, beginning with *bouillon au tapioca*, proceeds through each dainty stage—*galantine et jambon, jardinière de légumes, gigot, tarte aux fruits*—to its consummation, *café*. Truly, says the doctor, "good cooking is the best aperitif!" And the patient has good wine, too, if he so desire. The medical, nursing, and auxiliary services are carried out on a fairly lavish scale—100 of a staff for 318 patients

An important part of the volume is devoted to the lessons learned during these 20 years or so of sanatorium experience, and there is much of practical help in the matter of treatment, of tuberculin, to which the author assigns a definite though perhaps subordinate rôle, and of artificial pneumothorax The doctrine of auto immunisation through exercise and work, graded or not, is accepted with strict limitations, and the value of rest is emphasised and again emphasised. The man who delights in recording physical findings by the aid of coloured pencils and a multiplicity of dots, strokes, and demi-semiquavers will find everything to hand at Bligny, but, incidentally, the two chest diagrams in routine use there seem to us among the clearest and most convenient we have seen. The selection of patients is not too rigid, but it is Dr. Guinard's opinion that the period of treatment at a sanatorium is ordinarily too short, and he supports his opinion by some figures which, though not free from fallacy, seem to show that the after-results of treatment as expressed in terms of survival depend largely on the rest and the prolongation of stay in the sanatorium. The formation of a society of past and present patients, who meet annually at one or other sanatorium, with small subscription and numerous generous donations from the outside, enables the sanatorium to carry out some at least of the functions of a care association, and is a source of intense encouragement to those still undergoing treatment. The book is a splendid record of sanatorium work under a director whose heart and soul are in it, and might well form a guide to public and other authorities in this country who contemplate the erection and equipment of an institution which soars above the mere acquisition of a dismantled country-house and the throwing together of a few more or less dilapidated shacks with scanty staff and still scantier facilities for treatment At Bligny are sanatoria of which the personnel may be proud, served by a whole hearted devotion which spells success.

## THE EAST AFRICAN MEDICAL SERVICE.

THE Council of the British Medical Association has now expressed the definite opinion that members of the Colonial Medical Services "can no longer place any confidence in the fulfilment of the terms on which they are appointed by the Secretary of State." This conclusion has been arrived at on the grounds that certain things have taken place in the East African Medical Service which may prove a precedent for similar happenings in West Africa or in the West Indies; and the two alterations which are considered by the British Medical Association to be prejudicial to the position of medical officers are the possibility of transfer when a permanent domicile had been promised or assumed, and restriction of private practice when the opportunities for such practice had been put forward as an argument for joining the services We have received a copy of *East Africa*, a weekly journal published in London for the particular benefit of all having interests in East and Central Africa, and note therein a letter from a special correspondent in Nairobi which gives a view of the matter held by residents in Kenya.

"The action of the Colonial Office," he writes, "in amalgamating the several medical services of East Africa without notice to or the consent of the representatives of this colony is regarded here as a distinct breach of the promise that no steps towards federating the different territories should be taken without consulting Kenya's European inhabitants. This scheme also does not appear to be popular with the officers of our medical department, most of whom are comfortably domiciled in the colony, understand its conditions, and are naturally averse to transfer to distant, unfamiliar surroundings At the request of our elected members, representations are to be made to the Secretary of State for the Colonies about this decision. It is said here that the somewhat autocratic action already taken is due to the suggestions of some previously unheard-of advisory medical council."

---

[1] La Pratique des Sanatoriums d'après les vingt premières années d'exercice des Sanatoriums de Bligny By Dr L. Guinard, Médecin Directeur One volume of 418 pages with 31 illustrations in the text and 12 plates Bibliography and Index. Paris Masson et Cie. 1925. Fr 60.

It is quite clear that if the medical officers in Kenya entered the service on the understanding that they were not liable to be transferred from Kenya, a change of domicile upon official orders will be a breach of their engagement. In the case of some colonial medical officers it is contended that when they accepted their positions they knew that they were liable to be transferred from area to area; such officers will, of course, be in a very different position from those to whom a permanent domicile had been promised. That unification of the Colonial Medical Services, which for many obvious reasons is desirable, implies the transfer of medical officers from one area to another seems certain, and those joining the Services under the new regulations will understand what the position is. For those who entered the Services under pledges of different things compensation will have to be found if they suffer individually, while the position at Kenya merits particular consideration.

## THE PROBLEM OF THE MONGOL.

FEW of the unsolved problems of psychiatry have excited so much interest and so many papers as that of the Mongolian imbecile. It is a problem that spreads into the realms of biology and anthropology as well as that of clinical medicine, and the fundamental ætiological question is how far the condition depends on the original composition of the ovum, and how far on the process and events of its development. The group is extraordinarily well defined and readily recognised; to examine one Mongol is to know all. Dr. R. M. Stewart, at a recent meeting of the Section of Psychiatry of the Royal Society of Medicine, gave a vivid word-picture of the Mongolian idiot that left no room for disagreement. The cranium is brachycephalic, small and smooth, with flattening of the occiput and, to a less degree, of the face. The well-known epicanthic fold is common in infancy, but is less common than an oblique fold of loose skin just above the upper lid. This formation appears to be due to a failure of the nasal bones to develop, which produces the short squat nose with depressed bridge and narrow forward-looking nostrils. The superior maxilla is also under-developed, and the palate is high and narrow; nasal catarrh and guttural speech commonly result. The prominent malar bones so characteristic of the racial Mongol are practically never seen in the Mongolian imbecile. The eyes are small and often squinted, and ptosis, nystagmus, and eye-rolling are common. Dentition is late and irregular. Highly characteristic are the fissures on the protruded tongue, developed after birth. Dr. Stewart, however, had seen these in other types of ament, several of whom were congenital syphilitics. The scalp hair is wiry and sparse, but the coarse skin of the body is covered with downy hair. The hands are curiously soft, with thick clumsy fingers, and the palmar markings are characteristic. The fingers and toes are often webbed and the feet are broad, short, and clumsy, and their blueness gives evidence of the heart disease which is so common in this form of idiocy. The spine is remarkably straight and the abdomen prominent, and the lax ligaments allow unusual mobility at the joints, so that the young Mongolian imbecile naturally sits cross-legged like a Turk. Herniæ are almost constantly present.

There is some evidence that the incidence is increasing: Dr. F. C. Shrubsall was able to give an analysis of 310 cases dealt with in London. Nevertheless, of pathology there is practically none; Dr. Stewart was unable to quote a single instance in which the nervous system had been examined really thoroughly post mortem. The smallness and under-development of the cerebellum described by most observers can be correlated with the shortened base of the skull. Dr. Stewart drew attention to the frequency of binucleated Purkinje cells in the cortex of the cerebellum; these are also very characteristic of congenital syphilitic aments. He had found no abnormalities in the blood picture during life in a series of 28 adolescent or adult Mongolians, but in half the series there was a lymphocytosis. There was a marked hypotension of the arteries in all but four, most of them giving a systolic reading below 90. As Dr. R. Langdon-Down remarked in the course of the discussion, it is hard to believe that so fundamental a change, involving practically all the structures of the body, epiblast, hypoblast, and mesoblast, could be due to any accident in development during embryonic life. Nor will any theory depending on some chance combination of the germ-elements account for the striking difference of the Mongolian idiot from all the other members of its own family, while resembling so remarkably all other Mongolian idiots, nor for the special position of the Mongol in the family. The parents are usually getting on in years, and in Dr. Shrubsall's series the father was very often younger than the mother; in 78 of the cases there was hereditary tuberculosis, and in 67 acquired psychosis or psychoneurosis. But on the whole there is nothing in the family history of the Mongolian idiot to suggest an inheritance worse than the average. In default of any evidence against the mother, Dr. Dora Berry and others have tried to incriminate the father as "sexually defunct," and Dr. Shrubsall drew attention to the frequent history of a use of chemical contraceptives. This would correlate with the appearance of the idiot at the end of a large family, as in the past it has most often been the parents of several children who have resorted to the use of quinine and other contraceptive drugs which might poison the developing embryo. This leads on to Jansen's theory of amniotic pressure, as the amnion would be most exposed to noxious influences at this period and its failure to develop might well compress the fœtus and arrest its development by raising the amniotic pressure. Jansen points out the similarities between anencephaly, achondroplasia, and Mongolian imbecility, and ascribes them all to this cause. The view that the condition is a Mendelian recessive and inherited as such lacks the evidence of adequate pedigrees. Perhaps the most-discussed theory of all is that of atavism recently put forward by F. G. Crookshank. For him it is the Mongolism rather than the idiocy which it is important to stress, and most observers agree that Mongol traits are often seen in the parents of the Mongolian imbecile. It may be that these act as determining factors; if such parents are going, for other reasons, to have an imbecile child the imbecility will take the Mongol form. The resemblance between the Mongol and the cretin has naturally produced an endocrine theory, but no pathological evidence has been obtained in support of this beyond the gonadal changes common in all cases of arrest of sexual development. The basal metabolism of the Mongol shows no abnormalities. There are, however, as Dr. W. A. Potts pointed out, people who believe that Mongolism can be prevented by administering thyroid and ovarian extract to the mother during pregnancy. It is difficult to understand how prophylaxis can be applied in any sense scientifically to so capricious a thing as Mongolism. A Mongol may be born of a perfectly healthy mother as her first, last, or intermediate child; both parents may be at the zenith of their reproductive power and subsequent children or even a twin may be perfectly normal. This very caprice has led to the syphilitic theory of its ætiology, as syphilis is known to act in just such an unaccountable way on mother and offspring, but neither Dr. Langdon-Down, Dr. Potts, nor Dr. Shrubsall were able to find any evidence for syphilitic inheritance in the majority of their cases.

It will be seen that the discussion merely served to intensify the darkness which surrounds this interesting subject. In many instances where several theories have been put forward it has been found that all had some measure of truth, but it seems unlikely on the face of it that a condition with such striking and well-defined features as Mongolian idiocy will prove to be the resultant of a series of ætiological influences.

## INSURANCE FOR EDUCATION

THE Educational Facilities Association has put out a scheme aiming to ensure the education of boys and girls in the event of their father's death, and all professional men, doctors among them, will find much that is attractive in the idea. Briefly, the scheme provides that for a small premium per term, in the event of the insured parent dying, the fees of a pupil at the school attended shall be met until the child is ready to leave. It is proposed that the premium shall be paid to the headmaster with the ordinary term fees, the first payment being made when the pupil enters the school. Preparatory, secondary, and public schools are included in the range of the scheme. A school, acting on behalf of a group of parents, will make the necessary arrangements, through the Educational Facilities Association, with an insurance company. At preparatory schools the benefits will be available for pupils up to the age of 14; at public and secondary schools up to the age of 18. Broadly speaking, the insurance can be effected for a premium of £1 on every £40 paid in school fees. It will be possible, in addition, to make special arrangements to insure a child's continuous education from preparatory to public school, and from public school to university. Those who are familiar with the organisation of Epsom College, and the splendid work that is done by the College in securing educational facilities for the children of dead or disabled medical men, where no provision has been possible for the purpose, will be in full sympathy with the idea. So long as the doctor's income is maintained he is able to support his children at school, but with the cessation of professional earnings in a large number of cases there is no income available to complete the upbringing of children in the manner which had been rightly planned for them by thoughtful parents. Any methods which will help to ensure for such children continuous education should appeal to all our readers. But while in accordance with this scheme they are paying a premium upon the school fees of children, they should support by subscriptions Epsom College, remembering that there will still be many children of medical men in whose case there will be difficulty in providing the premiums necessary to take advantage of the scheme of the Education Facilities Association.

## A VARIOLOUS STORY.

AT a time when it is difficult to induce the population of this country to be vaccinated, it is refreshing to hear of the enthusiasm shown by the natives of a village in Palestine for even more drastic measures. In an entertaining article which we publish on page 212, Dr. J. Macqueen tells how he investigated a case of small-pox in a village in Palestine and took elaborate precautions for its isolation. He satisfied himself that there was no other case in the village, but it was not long before he learnt to his astonishment that the local medicine-man had taken the opportunity to engage in a little prophylactic work and had already inoculated 300 children with variolous material from this case. The practice of variolation is extremely ancient, but it was not apparently until Lady Mary Wortley Montagu had her son variolated in Constantinople in 1717 and described the procedure in her correspondence that it became popular in England and America. The method adopted in Turkey was to remove the contents of a vesicle (not pustule) and introduce it by means of abrasion, incision, or puncture. The material obtained from an inoculated case was preferred. The usual Chinese procedure was to plug the nostril with cotton which had been saturated with a mixture of water and pustular crustaceous matter taken from the eruption of a small-pox patient. Less commonly, fresh crust was powdered and blown into the nostrils through a bamboo pipe. The method in vogue in Palestine is to puncture the skin with a thorn through variolous matter spread on the surface. These various practices could only have remained popular because their effects were milder than true small-pox, and the death-rate cannot have been more than 1 per cent. or it would hardly have been tolerated in England. Why variola inoculata should be milder than variola vera does not seem altogether clear. Although, admittedly, virus introduced under the skin may find itself in an unfavourable medium for propagation, it might have been supposed from the recent work of Dr. Mervyn Gordon that inoculation through the mucous membrane of the nose would produce severe infection. In the Palestine experiments it seems probable that not all the inoculated persons were treated with virulent material, although the activities of the local doctor in Dr. Macqueen's story had sufficiently sensational results. Of the 300 children inoculated death occurred in 8·8 per cent. of those which developed an eruption, and in 3 3 per cent. of the whole number inoculated. But it is not to be supposed that this traditional practitioner roused against himself the fury of an antivariolation society. On the contrary, he seems to have gained nothing but kudos for his work, and certainly did not lose repute by the month's imprisonment which was its sequel. As Dr. Macqueen concludes, this Dawaimeh epidemic will have served some useful purpose if it acts as a reminder that a disease, variola inoculata, was once extremely popular; that Jenner superseded it with a better—vaccination; and of the problem why small-pox is such a severe infection when naturally acquired, so much less severe when inoculated, and so wonderfully harmless when passed through the calf. (It will be recalled that Dr. Gordon [1] thinks it probable that the vaccinia virus contains approximately equal quantities of the elements which produce cow-pox and small-pox—an opinion which supports those of Jenner.) As for Dr. Macqueen's narrative, it is possible to read between the lines that a difficult and threatening situation was met by him with skill, tact, and firmness. Even with such enthusiastic variolophils it was no mean achievement to get them to parade for a third vaccination.

## THE NATIONAL INSTITUTE FOR THE DEAF.

THE National Bureau for Promoting the General Welfare of the Deaf was founded some 15 years ago by Mr. Leo Bonn, and for a number of years accomplished valuable work. Even during the war period when, like those of many similar organisations, its activities were half paralysed by the loss of expert assistance, its main object was kept steadily before the public. The need for a national recognition of the position of the deaf has long been urged by the supporters of the Bureau, and two years ago a movement for its reconstitution was started. This movement was publicly inaugurated at a conference in March, 1924, under the presidency of Lord Charnwood, when the outlines of the reconstituted body were considered and an executive committee was appointed to prepare draft articles of association. At this meeting Lord Charnwood was unanimously elected president of the reformed organisation; a representative group of vice-presidents accepted office, and an executive committee was selected to carry on industrial and social welfare work, to watch finance, to discharge generally the purposes of the Institute, and to coöperate with a strong medical committee. Mr. A. J. Story, headmaster of the North Staffordshire School for the Blind and Deaf, accepted the position of secretary, and those who know the work which he has done on behalf of the deaf will recognise the good fortune of the new organisation, now entitled the National Institute for the Deaf, in obtaining his services.

The report of the first year's working of the Institute has been circulated recently and shows that a great deal of preliminary spade-work has been accomplished, and in so short a space of time little more could be expected. The executive committee has been studying closely the industrial position of the deaf, the facilities—such as they are—that exist for their institutional treatment, the scope of any trusts or charities for their benefit, and any provision that exists for the instruction and supply of competent teachers. Apart from the record of performance the report makes interesting, if pathetic, reading because of the numerous and important places where the need for activity is demonstrated in order that the deaf subjects may have proper opportunity to prove their high measure of capacity to make good in life, given the necessary help at the start. The good objects of the Institute are clearly set out in the report and the promise at the beginning is fruitful, so that the necessary funds to carry on the work ought surely to be found. At present the Institute has an income of about £650 per annum, and one of at least £2000 is required to carry on the current work. If the facts set out in the report are realised by even a small section of the general public, annual subscriptions far in excess of this modest want would be forthcoming. And a much greater sum could be used immediately and with certain results.

---

[1] THE LANCET, 1925, ii., 826.

## VITAL STATISTICS FOR ENGLAND AND WALES DURING 1925.

THE Registrar-General has issued a provisional statement of the figures for birth-rate, death-rate, and infantile mortality (per 1000) during the year 1925.

| — | Birth-rate. | Death-rate. | Infant mortality-rate. |
|---|---|---|---|
| England and Wales .. .. | 18·3 | 12·2 | 75 |
| 105 county boroughs and great towns, including London .. | 18·8 | 12·3 | 70 |
| 158 smaller towns .. .. | 18·3 | 11·2 | 74 |
| London .. .. .. .. | 18·0 | 11·7 | 67 |

The smaller towns are those with an estimated population in 1921 of 20,000–50,000. The (crude) death-rate for England and Wales relates to the whole population, but that for London and the groups of towns to the civilian population only. The Registrar-General remarks that the birth-rate of England and Wales, as a whole, is the lowest recorded, except during the war years 1917 to 1918. The death-rate and infantile mortality rate are equal to those recorded in the previous year. These provisional figures, which are not likely to require substantial modification, have been issued for the information of medical officers of health.

THE first number of the Registrar-General's Weekly Return of Births and Deaths for 1926 is unchanged inside, but has a cover whose phrasing gives a more accurate idea of its contents, which include a topographical list of infectious disease notified in England and Wales. The welcome reduction in the price of the Return from 1*s.* to 6*d.* weekly should ensure the wide circulation which this invaluable document deserves.

## INDEX TO "THE LANCET," VOL. II., 1925.

THE Index and Title-page to Vol. II., 1925, which was completed with the issue of Dec. 26th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLVII.—THE TREATMENT OF SALPINGITIS.

### I.—ACUTE SALPINGITIS.[1]

ACUTE salpingitis for all practical purposes is either gonococcal or streptococcal, and the latter nearly always follows labour or abortion. Further, whilst in gonococcal infections the inflamed tube is the one important feature, in the streptococcal cases the tubal lesion is only an incident in a widespread pelvic inflammation. Acute gonococcal tubes always arise as a spread of infection along the mucous membrane from the uterus to the tubes, whilst in streptococcal cases the tubal infection is secondary to a pelvic peritonitis, the organisms gaining access to the tubes either by the lymphatics or via the abdominal ostium. Thus it happens in practice that treatment is directed towards the tubes primarily in gonorrhœa, but towards a widespread but local peritonitis in streptococcal puerperal infections, the tubes being only of secondary importance.

### *Diagnosis.*

In gonococcal cases much depends upon diagnosis. The diagnosis is often of great difficulty, the differentiation from acute appendicitis raising a problem very baffling to the surgeon. The localisation of pain to the right iliac region is not always so marked a feature of appendicitis as might be expected, nor is the pain of acute salpingitis always bilateral at first. In both diseases there may be involvement of large areas of peritoneum producing more or less generalised pain in the lower abdomen. The temperature, pulse-rate, and the occurrence of vomiting present nothing characteristic of either lesion. At the commencement of an attack, when time is so important in appendix cases, there may be nothing definite to be felt on abdominal or pelvic examination. On the whole, there is more to be discovered by a pelvic examination in acute salpingitis than there is in appendicitis. One particular sign is of great importance, and that is the acute pain which is evoked by attempts to move the uterus in tubal inflammations. Although not fixed at first, any movement of the uterus always produces great pain and is much resented by the patient. This is not so in most appendix cases, as long as the appendix and surrounding inflammatory focus are situated above the pelvic brim. In doubtful cases an examination under an anæsthetic should never be omitted, since it will often decide the diagnosis, bilateral thickening of the tubes and of the structures around them, definitely excluding appendicitis.

Another condition sometimes mistaken for salpingitis is a ruptured ectopic gestation, or tubal abortion. The history of the latter often decides the diagnosis, especially if a period has been missed, which is not always. The very rapid onset, the sudden pain and faintness, followed by a rapidly rising pulse-rate from internal hæmorrhage, and later the onset of vaginal bleeding (very important) make a clinical picture sufficiently pathognomonic of ectopic gestation and its acute results.

### *Operative versus Conservative Measures.*

Once the diagnosis of acute gonococcal salpingitis is made, the question has to be decided whether an operation is to be performed or not. Seeing that the peritoneal inflammation which determines the acute attack is always localised, and that the risk of general peritonitis is practically nil, there is never the same necessity for immediate operation as there is in appendicitis. Moreover, the natural tendency first attack of gonococcal salpingitis is towards spontaneous cessation of symptoms and resolution of inflammatory peritoneal exudates in about a fortnight.

---

[1] An article by Mr. Stevens on the Treatment of Salpingitis will appear in the next issue of THE LANC

The condition of the tubes, ovaries, and peritoneum after the attack has subsided varies enormously; in the majority of cases both tubes are enclosed in adhesions, with their abdominal ostia permanently closed. In a small proportion of the cases one or both tubes may remain patent and perform their normal functions, as shown by the occasional occurrence of pregnancy later. In another small percentage of cases the symptoms only ameliorate, the pulse and temperature never become normal, and on examination the tubes are found obviously enlarged, meaning that they contain pus These are the only cases in which operative measures are imperative, and in them only when it is obvious that complete resolution has not taken place.

Certain authorities recommend immediate operation in all cases, the chief argument in its favour being that a large proportion of gonococcal cases suffer from recurrent attacks of pelvic peritonitis, that adhesions become more dense and widespread with each attack, that operations have to be done in the end, and that these late operations are more difficult and dangerous. These arguments are only partly true, for some cases never have recurrent attacks at all, others do not get very dense adhesions, and, on the whole, however difficult the late operation may be, the results are very good and the mortality is low. If an operation is done in the acute stage of a first attack the temptation to remove both tubes is very great, especially as they are usually enlarged and dripping pus from the abdominal ostium. It has been shown, however, that it is not necessary to remove these pus-dripping tubes. If they are freely slit up and the pelvis drained, preferably by a large tube through a small stab wound outside the rectus muscle, the results are very good. This is the treatment recommended if the abdomen is opened in a case in which it is doubtful whether the appendix or tubes are at fault, as will certainly happen on occasion to every surgeon The histories of cases treated in this way will decide in the future whether tubes slit open will ever function normally, or whether there will be such widespread adhesions that conception is impossible. Further, also, it is not yet certain whether cases thus treated can be regarded as cured, or whether they may later have recurrent attacks of peritonitis. From these considerations it is advised that a first attack of acute gonococcal salpingitis and peritonitis should be treated on expectant lines, and operations only performed if complete resolution does not occur, and actual pyosalpinges remain. In the latter event an abdominal section must be done, taking care to pack off the intestines with a large swab or gauze roll to prevent any possible infection of the upper abdomen. Usually, both tubes will have to be removed, which can only be regarded as a calamity, especially as these conditions usually occur in young women. If it can be shown that these recent pyosalpinx cases can be treated safely by slitting up the tubes and drainage, true conservatism will be reached, and some of these tubes may recover sufficiently well to perform their functions. In all operations of this kind, where there is infection and where drainage is necessary, only absorbable catgut should be used as a ligature or suture material, so that there may be no sinus formation from infected ligatures.

### *Expectant Treatment.*

The expectant treatment to be adopted is chiefly concerned with the relief of pain and the promotion of absorption of inflammatory exudates. Pain is best relieved by hot applications to the abdomen and hot vaginal douches of normal saline solution. Later, when pain is subsiding, counter-irritation may be employed in the form of ichthyol tampons or vaginal suppositories, also combined with hot douches, 10 per cent. ichthyol in glycerine for the former or 10 per cent. ichthyol in cacao butter for the latter being the usual method of prescription. Every other night is sufficient for the ichthyol, as it is easy to create a sore vagina by too frequent applications. At the commencement drugs are required to relieve pain, and heroin in small doses (gr. 1/12) answers very well; later, aspirin gr. x. and potassium bromide gr. xxx. by the mouth will suffice. The bowels must be kept open by enemata, and if necessary saline purgatives may be given. Absorption is promoted by hot-air baths, easily contrived in a private house by making a rough cradle to go over the abdomen and hanging in it two carbon filament electric lamps.

### *Acute Salpingitis of Streptococcal Puerperal Origin.*

This is a minor consideration in itself, being quite overshadowed by the degree of local peritonitis present, and the almost constant lesion, ovarian abscess, accompanying it. Puerperal peritonitis is frequently generalised, and as such is practically always a fatal condition, it will not be considered in this article. If, however, the disease is localised, it may subside and resolve like the gonococcal variety. Frequently, however, this desirable result does not occur and suppuration results. In this event three conditions may have to be dealt with: free pus in Douglas's pouch, pyosalpinx which may be unilateral, and ovarian abscess. These lesions often cannot be differentiated before operation and often coexist. Sometimes free pus alone is found, in which case the posterior vaginal fornix will be found bulging downwards, the uterus being pushed upwards and forwards. In such a case the pus is best evacuated per vaginam. An incision is made transversely across the posterior fornix for one and a half inches, the finger is pushed up behind the uterus and the abscess cavity is entered. Blunt-pointed curved scissors may be used instead of the finger. A careful bimanual examination of the pelvis with the finger in the abscess cavity will decide whether there is an ovarian abscess in addition. If present, it is to be opened into the abscess cavity. Drainage is best accomplished by two tubes, side by side, sutured in place by fine catgut. Through them the abscess can be irrigated daily if they are left long and reach the vaginal entrance. In other cases where the temperature and pulse, wasting, and leucocytosis indicate pus formation, but no definite pelvic abscess can be felt, an abdominal operation must be done. Great care should be exercised to prevent general peritoneal infection, adhesions should be separated by cutting as much as possible. If the ovary is represented by a sac of pus it should be removed whole if possible, a pyosalpinx removed and drainage always employed whether any free pus is found in the peritoneum or not. As these cases are always the result of lymphatic infection from the placental site they are quite often unilateral, the appendages on the other side being unaffected. In a case of mine a normal pregnancy occurred three years after the removal of a large ovarian abscess, a pyosalpinx, and drainage of the resulting cavity. One trying complication of these cases is suppuration and breaking down of the abdominal incision This can sometimes be prevented by protection of the wound surfaces during the operation by rubber sheeting, and by swabbing the wound with a non-irritant antiseptic such as Milton before suturing. Drainage should always be carried out through a stab incision lateral to the mid line so as to allow of complete closure of the central incision.

THOS. G. STEVENS, M.D., B.S. Lond., F.R C S. Eng.,
Obstetric Surgeon, St. Mary's Hospital Gynæcological Surgeon, Hospital for Women, Soho-square

---

A GLASGOW NURSING HOME.—Dr James Macfarlane, chairman of the Board of Glasgow Royal Infirmary, and his brother, Mr George W Macfarlane (both of Messrs. Macfarlane, Lang and Co., biscuit manufacturers of Glasgow), have presented that institution with 22 acres of land at Canniesburn, on the north western outskirts of the city, as the site for a nursing home for those requiring treatment outside their own homes whose means do not allow of their paying the ordinary charges.

# Special Articles.

## THE PRESENCE OF LEAD AND ARSENIC IN TARTAR EMETIC.

BY E. GRIFFITHS-JONES, M.SC. MANCH., A.I.C.,
CHIEF CHEMIST, PUBLIC HEALTH LABORATORIES, DEPARTMENT OF PUBLIC HEALTH, CAIRO.

THE extensive use of potassium antimony tartrate, injected intravenously, in the treatment of bilharzia lends fresh importance to the question how far the elements lead and arsenic should be allowed in the drug. Some idea of the importance to which tartar emetic has attained may be gathered from the number of patients to whom it was given last year in Egypt. In all 54,316 patients were treated and the total number of intravenous injections was 311,656. The amount injected each time is 2 c.cm. of a 6 per cent. solution, and each patient receives in the whole treatment approximately 1·5 g. of tartar emetic.

Early in its use it was found that occasionally very severe symptoms arose as the result of the treatment, and it became incumbent on those concerned, before holding the tartar emetic responsible, to make certain that the unpleasant after-effects might not be due to some impurity in the drug used. In accordance with routine practice samples of tartar emetic were examined in these laboratories before being issued for use to the hospitals. The department is accustomed to insist that pharmaceutical preparations should conform to the requirements of the British or other recognised pharmacopœia.

It was very early established that several specimens of tartar emetic submitted for analysis contained either lead or arsenic or both. For many drugs the B.P. lays down a definite limit for lead and arsenic, and gives details of the examination for these impurities. There is accordingly no difficulty in accepting or rejecting such drugs, but tartar emetic is not included amongst those for which a lead and arsenic limit is given. The wording of the British Pharmacopœia (1914, p. 48) is as follows: "Yields no characteristic reactions for lead, copper, arsenic, iron, sodium, ammonium, chlorides, or sulphates."

Two leading firms of manufacturing chemists, one in England and one in Germany, have written to the department of Public Health, Cairo, on this question, and both adopt the same attitude in quoting the above paragraph from the B.P. in their favour. The British firm admit the presence of lead, but argue that all samples of tartar emetic, of different makes, which they have examined, contain 0·09 to 0·12 per cent. of lead; the German firm of manufacturing chemists say that their tartar emetic is lead-free and that, if it is not, there is no method of estimating lead in tartar emetic. The German firm argue in effect that if 1 g. of tartar emetic be employed and this quantity examined for lead by the tests given in the B.P., p. 492, no reaction will be obtained which will settle the presence or absence of lead. The contention of both these firms that tartar emetic should be examined for lead by the tests given on p. 492 of the B.P. is extraordinary in view of the obvious fact that the antimony would interfere with their application.

We have employed two methods for the estimation of lead, one colorimetric and one gravimetric. The colorimetric test is given in Squire's Companion to the British Pharmacopœia, p. 213. Twenty parts per million of lead will give an appreciable colour.

In order to make certain that the colour was due to lead and not to any other metallic impurity we have in certain cases estimated the lead gravimetrically, and for this I have worked out the following gravimetric process, which I believe to be accurate though somewhat tedious:—

20 g. of the sample were dissolved in a minimum quantity of water and then decomposed with a strong solution of caustic soda, the latter being added until the white precipitate formed had redissolved, after which a further excess of soda solution was added. $H_2S$ gas was passed into this solution during several hours and the beaker then allowed to stand overnight. The black precipitate which had settled was filtered through a Gooch crucible, washed with ammonium sulphide, and finally with water. The precipitate was dissolved in dilute boiling nitric acid. Sulphuric acid was then added and the solution boiled until it commenced to fume, after which it was cooled, diluted, and allowed to settle.

The white precipitate which settled was filtered through a Gooch crucible and washed with 10 per cent. sulphuric acid and finally with water.

In some experiments this precipitate was assumed to be lead sulphate and weighed as such after drying. In others the precipitate of lead sulphate without drying was dissolved in a hot concentrated solution of ammonium acetate and the lead in the filtrate was precipitated with potassium bichromate solution as lead chromate. This solution and precipitate were boiled, cooled, and allowed to settle, and the precipitate was filtered on to a Gooch crucible, washed with water, dried at 110° C. and weighed as lead chromate.

In one case a sample was reported to me as containing 200 parts per million of lead when examined on 1 g. colorimetrically. By the gravimetric process I obtained the figure 198·7. In another case the report was "about 1200 parts per million." Determined gravimetrically the figure was 1206.

For detecting arsenic the U.S.P. and the P.G. employ Bettendorf's test, a colour reaction with stannous chloride, which depends upon a darkening of the reagent within a specified time if arsenic be present. The test is not very satisfactory, especially in view of the fact that the U.S.P. employ 0·1 g. of the tartar emetic and the P.G. 1 g.

The following method is used in these laboratories and appears to be reliable:—

0·5 g. tartar emetic is dissolved in 5 c.cm of water; 17 c.cm. strong HCl are added and the solution is transferred to a small distilling flask, when one or two drops of strong solution of stannous chloride are added.

The solution is distilled until only a few c.cm. remain. An adapter from the condenser dips into a very small quantity of cold water to absorb the HCl gas which first passes over. The distillate is redistilled, the last few cubic centimetres being rejected, and the second distillate is transferred to a suitable vessel; the arsenic, if any, is estimated by the Gutzeit process against a standard stain.

The limit which we have adopted for arsenic is 10 parts per million as estimated by the above process. The quantity of the limit of lead has aroused much controversy, but we maintain that lead-free tartar emetic can be obtained, that is to say, a salt which shows no colouration on 1 g. with NaOH and $H_2S$ as described above. It is surely possible that even small amounts of lead—say, 50 parts per million—might produce toxic symptoms when injected intravenously in conjunction with antimony.

---

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Jan. 28th Dr. H. C. Cameron will lecture on Catarrhs and the Catarrhal Child at 5 P.M. in the lecture hall of the Medical Society, 11, Chandos-street, London, W. The London Lock Hospital will hold a comprehensive course in Venereal Diseases from Feb. 1st to 27th, including clinical instruction and lectures. A two weeks' afternoon course beginning on Feb. 1st will be given at the Blackfriars Hospital for Diseases of the Skin. A combined course in Diseases of Children, in which the Paddington Green Hospital, Victoria Hospital, and the Children's Clinic will be participating, will be given from Feb. 8th to 27th. There will be morning and afternoon sessions in all the different departments of the hospitals. A late afternoon course (4.30 to 6) has been arranged at the London Temperance Hospital from Feb. 8th to 19th for the convenience of the general practitioner. A general intensive course in medicine, surgery, and the special departments will be held at the Queen Mary's Hospital, Stratford, from Feb. 15th to 27th. Daily sessions will be given at 10.30 A.M. to 5 P.M., including demonstrations of clinical methods and groups of illustrative cases. The syllabus of each of these courses, and the programme of the general course, may be had on application to the secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

### REPORT OF THE
# MEDICAL RESEARCH COUNCIL,
### 1924–25.

THE eleventh annual report of the Medical Research Council[1] follows its immediate predecessors in general pattern. After an introductory comment on special aspects of the work under review, an account is given of the present constitution and activities of the National Institute for Medical Research at Hampstead. The next section is devoted to problems concerned with the determination of biological standards and the methods of biological survey and measurement, this year in relation to the provision of machinery for the operation of the Therapeutic Substances Act, 1925. Experimental medicine, notably the work carried out in the clinical units of various medical schools, is described in Section IV. Research schemes in special subjects form the substance of the longest section of the report. Though this grouping has only a temporary and provisional value, and must not be regarded as a permanent or rigid division, it serves as a convenient index to all sections of the report, since work already described on another page in connexion with various institutions is mentioned again in its appropriate paragraph. The system of cross references is well devised and is used with discretion. Notes on industrial medicine and industrial fatigue, on travelling Fellowships, and on changes of personnel in the Council conclude the report, while an appendix gives lists of standing committees, personal names, institutions, and subjects dealt with.

### *Constitution and Finance.*

The constitution of the Medical Research Council is at present as follows. The Earl of Balfour, F.R.S. (chairman), Lord Mildmay of Flete (treasurer), Mr. William Graham, Sir Frederick Andrewes, F.R.S., Prof. E. P. Cathcart, F.R.S., Prof. Georges Dreyer, F.R.S., Prof. T. R. Elliott, F.R.S., Sir Archibald Garrod, F.R.S., Sir Charles Sherrington, F.R.S., Sir Cuthbert Wallace, and Sir Walter Fletcher, F.R.S. (secretary).

A grant-in-aid of £135,000 was provided by Parliament for the expenditure of the Medical Research Council during the present financial year. This sum will be allocated as follows: For administration, including expenses of the Council, of the administrative offices and staff, and of travelling, £8,500. For the expenses of the National Institute for Medical Research at Hampstead and of the farm laboratories at Mill Hill in association with it, for the salaries of the scientific staff and the expenses of research work done by them or by other workers temporarily attached, £12,000. For research grants to scientific workers and for the expenses of their researches at the universities and at other centres in the United Kingdom, for research work in clinical medicine, for various statistical inquiries, and for the investigations of the Industrial Fatigue Research Board, £81,500.

The Council acknowledge with gratitude that in the past resources additional to their Parliamentary grant-in-aid have been available for their use, either by the coöperation of other bodies or by the generosity of individuals.

Last year an introductory chapter was devoted to a survey of progress in physiology, pathology, and bacteriology in the years 1920–24. This year a critical discussion of the advances made in the year under review in the study of immunity and infectivity in general, in the investigation of the filter-passing viruses and of cancer, and in the determination of biological standards is supplied. The chapter gives a well reasoned statement of the present position and outlook, which we print substantially in full.

### *Immunity and Infectivity.*

No phenomena are more obvious and striking than those of the immunity won by the body after a first successful defence against a given infective organism, and no triumphs of medical science are greater in terms of humanitarian utility than those successful empirical imitations of this natural process which have given us the means of a broadcast anticipatory defence against small-pox, cholera, typhoid fever, and the like. This study of immunology has naturally attracted the eager efforts of workers in all countries, and immense accumulations of data have been collected. The scientific analysis of immunity reactions, however, offers extraordinary difficulties. Some of these reactions belong to the leucocytes, the wandering defensive cells of the body. The study of these, even in normal life, has been much neglected by physiologists, and this defect has been only partly remedied by the acute observations of pathologists who have studied them in disease. The experimental investigation of them, however, is a matter of extreme difficulty. It must still be uncertain how far, for instance, in the ingenious studies recently made in the service of the Council by Sir Almroth Wright, the behaviour of leucocytes under artificially controlled conditions outside the body is truly representative of their behaviour within the body. Not less difficult is the study of the immunity responses of the body shown in changes of the chemical and physical states of the complex fluids of the body. In this field has been studied the precise adaptation, the "specificity," of the chemical responses made to the attack of particular organisms of given type, or even of sub type. Elaborate studies have brought into use names descriptive of particular parts of these phenomena, the so-called "aggressins," "agglutinins," "precipitins," and the like, into which these defensive chemical mechanisms can be sorted. That so much has been accomplished in the present imperfect state of biochemistry and colloidal physics is high testimony to the experimental skill of the pathologist. It seems clear, however, that for further clarity in these matters, for the explanation of disturbing contradictions, and for the issue in practical use of methods of precision, we must look to the better development and application of chemical and physical knowledge. This indeed is already in sight. An instance of it, among others that might be quoted, is ready to hand in the piece of work by Dr. H. W. Dudley and Dr. P. P. Laidlaw in the National Institute for Medical Research. Here it has been shown that part of the specific reaction of the body fluids to the tubercle bacillus and its products can be elicited by a relatively simple chemical substance of recognisable molecular structure. Advances of this kind, small as they may seem at present, are greatly needed for clearing away the ambiguities and disappointments that have attended all the efforts from those of Koch to those of the present day to secure at will an effective, regular, and measurable artificial immunity, whether in active or passive form, against tuberculosis.

Meanwhile, it has been interesting in recent years to notice an increasing study of the "infectivity" of the organism as contrasted with the immunity responses of the host. Intensive study is being made of the exact chemical conditions which either advance or retard the growth of the infective bacteria and the development in them of higher offensive powers or "virulence," and of the products of bacterial growth. Instances may be found of studies in this field by several workers with Sir Frederick Hopkins in biochemistry and by Dr. E. G. D. Murray in pathology, all at Cambridge, and by Prof. J. W. McLeod at Leeds.

On another side some striking recent studies have been made in this country which show the dependence of the infectivity of bacteria upon what at first sight seem to be almost irrelevant factors acting in necessary alliance with them. For a quarter of a century it has been known that some, perhaps many, of the microbes which are undeniably responsible in a causal sense for definite and grave diseases in man animals are in themselves completely

---

[1] H.M. Stationery Office. 1925. Pp. 184. 3s. 6d.

Introduced to the body in the absence of other agents they are quite harmless. Thus the bacilli of tetanus or their spores, if washed and implanted alone in the body, cause no ill-effects. Mr. C. Dobell showed that the amœba which causes amœbic dysentery is a common inhabitant of the human intestine in those who have never been outside this country; yet amœbic dysentery very rarely occurs in Great Britain. In disease due to organisms of several, perhaps of very many, kinds, the disease begins only if special circumstances are present, in which some change in the body, due to some other factor than the infecting parasite itself, has been brought about.

During the war Dr. W. E. Gye and Dr. W. Cramer studied this problem with immediate reference to wound-gangrene and tetanus. They discovered that a minute quantity of calcium salt, a common constituent of soil, acts on the body tissues in such a way that the otherwise harmless bacillus is able, with the accompaniment of this adjuvant chemical influence, to act with full virulence. Dr. Gye later showed, with Dr. E. H. Kettle, a parallel or analogous relationship between the infectivity of the tubercle bacillus and the effects of silica. The infective power of the bacilli, as shown by their unrestrained growth and its consequences to the host, was immensely increased if silica was associated with it in action upon the body tissues. This pursuit of a line of theoretic thought has immediate practical significance for the study and control of miners' phthisis, in which the most direct danger to life due to silicosis is that of the tuberculosis so constantly associated with it. Work of this kind must hold great possibilities in the future, and it will be seen that it has already assisted inspiration or at least provided suggestive analogies in the studies of cancer by Dr. Gye which have attracted so much attention in the past year.

### *Studies of Filter-passing Viruses and of Cancer.*

It has been shown by Dr. Peyton Rous, of the Rockefeller Institute, New York, in 1911, that a rapidly fatal malignant tumour in a certain breed of fowls can be caused by an agent so small as to be able to pass through very fine filters that would hold back ordinary bacteria. The agent was believed to be a filter-passing virus. Dr. Gye has now provided experimental proof that this opinion is true. In the first place, he has shown that the agent in question can be shifted in fluids containing it by very rapid rotary movement—and is therefore corpuscular; in the second place, he devised means for the first time to cultivate the organism artificially, and so to use it in isolation for experimental work. He found evidence that the cultivated and isolated germ could not alone produce a new tumour, but only in the presence of an equally essential second factor, a non-corpuscular and therefore a non-living and soluble chemical substance which could be obtained from the substance of the previous tumour. The ultra-microbe together with the chemical factor ("specific factor") regularly gave a new malignant tumour. The microbe itself is quite invisible by ordinary microscopic methods. Mr. J. E. Barnard, however, devised special means for demonstrating its presence and for gaining some first approximations to its description by using ultra-violet light. The success of this work and of other developments of optical technique allowed the presence or absence in given preparations of the virus, as demonstrated experimentally by Dr. Gye, to be detected independently, and thus each part of the work could provide a check upon the results of the other. The possibility of this cross-checking of the results gained on either side and its uniform success greatly increased confidence in the results obtained. The preliminary results were published in THE LANCET[2] by Dr. Gye and Mr. Barnard in companion papers last July upon the Ætiology of Malignant New Growths.

This new work transforms our outlook upon the general problem of the causation of cancer. Observation, gross and microscopic, has shown beyond dispute that malignant disease occurs in almost all animals. Through all the range of the animal kingdom it begins in the same way in the form of a local swelling, almost always single; it spreads in the same way by permeation locally and by carriage in the streams of the flowing body-fluids to set up more remote secondary tumours elsewhere; it ends in the same way, in the death of the host. Microscopically a given variety of cancer in man, say of the skin, is the same as a cancer of the same tissue in a mouse, or a dog, or any other animal. The disease presents in that respect a uniformity which is almost without parallel in pathology. Clinically and biologically it is an individual disease, maintaining its own characters whatever the scene of its being. The experimental study of cancer, however, has hitherto not revealed any *nexus* between the tumours of different species of animals. It has been found impossible, for instance, to transfer the tumour of one animal—e.g., of a mouse—to another mouse by any means except by transferring some of the living tumour cells; if the cells are killed by any means they can no longer reproduce the tumour. Moreover, the tumours of mice can even so be propagated only in other mice and in no other kind of animal. All attempts to show the existence of an agent separable from the living cells and able to reproduce the tumour have hitherto failed.

Experimental study had therefore indicated a particularity or specificity of malignant tumours, while clinical and general observation had seemed to establish a uniformity and generality. This has been the great paradox of medicine. Those who reflected exclusively from the clinical point of view were inclined, in general, to believe that some common causative factor must exist to link up the tumours of man and of the other animals; those who rested on the experimental findings tended, again in general, to reject such a belief. The evidence now brought forward by Dr. Gye resolves the paradox. In essence it suggests that the common factor for all malignant tumours is a filter-passing virus or ultra-microbe, or a family of viruses. It shows that this microbe alone is harmless, as the bacillus of tetanus is harmless in the absence of some other adjuvant factor. Only in special conditions, determined by another factor, can the microbe infect the body cells and institute a new growth, a tumour. Heretofore, it has been almost inconceivable that a separate form of cancer germ could exist to correspond with every race of animal and every different variety of tumour formation. If, however, the specificity resides in an adjuvant chemical factor derived from the tissue-cells of a given species of animal, specificity need not be postulated for the other essential agent—namely, the infective ultra-microbe or virus. It may be noted that among the conspicuous general circumstances which are well known to favour cancer production are those of long-continued irritation by tar and certain oils, chemicals like arsenic and aniline dyes, clay pipes, and so on. It may be found later that these apparently diverse contributors have a common mode of action and a common effective resultant factor.

The fowl sarcoma described by Rous is conspicuous among all transplantable animal tumours as being able to yield not only the virus or ultra-microbe but also a substance which determines "infection." The microbe can be replaced by microbes obtained from other tumours and from other animals. The demonstration of the truth of this is the essential feature of Dr. Gye's work, at this stage at least, and so far as the general cancer problem is concerned. It is a demonstration which the Council hope—and have reason to expect—will be repeated very soon in many laboratories in other countries.

It need hardly be pointed out that the establishment of a definitely parasitic causation of malignant disease brings new hope to the prospect of gaining further knowledge. Since an avenue is plainly open to the experimental confirmation and extension of these results, it is unnecessary, and indeed unadvisable, to speculate here upon the practical possibilities to which they may lead.

---

[2] THE LANCET, 1925, ii., 109 et seq.

The Council acknowledge indebtedness for material supplied to Dr Gye, to Dr. Peyton Rous, and to Dr J. A. Murray, F R.S., Director of the Laboratories of the Imperial Cancer Research Fund. The experimental work of Dr. Gye and the optical work of Mr. Barnard have been actively taken up by the staff of this Fund with a view to their extension in the many directions now open The proximity of the Stroud Laboratory of the Imperial Fund to the Council's Farm Laboratories at Mill Hill has greatly facilitated this coöperation. The Council are constructing additional laboratory accommodation at Mill Hill, to which, for the present at least, Mr. Barnard's department of Applied Optics, including the work upon ultra-filtration, will be moved from the National Institute at Hampstead The trustees of the late Sir William Dunn have generously given to the Council, for the promotion of medical science, £2000 a year for five years, and this will be used in chief part for the advancement of these studies.

### *Biological Standards.*

The enactment in August, 1925, of the Therapeutic Substances Bill is an event of much importance to the progress of medical science, to the daily practice of the medical profession, and to the safety of the public. The primary aim of the Act is to protect the public, both patients and doctors alike, by fixing standards for the strength and purity of complex substances like diphtheria antitoxin or like insulin, and, again, complex chemical compounds like salvarsan. These can only be assayed, or measured for their potency and purity, by indirect methods. Hitherto the doctor, betrayed by the absence of potency tests, has been in danger of quite inadvertently giving an overdose or underdose which may have serious or fatal results, or again, betrayed by lack of purity tests, he may often have exposed his patients to other dangers.

The arrangements proposed in the Act closely follow the present working arrangements for salvarsan and for insulin. These arrangements have only been made possible by the accident in each case that patent rights have been vested in a public department under which the enforcement of standards of strength and quality has been made possible. Salvarsan compounds have been manufactured and imported under licence from the Board of Trade owing to the outbreak of war in 1914, while insulin has been manufactured under licence from the Medical Research Council. All the salvarsan compounds since 1914, and all the insulin since its discovery in 1923, which have been used in this country have been tested for potency and purity by the Medical Research Council. By a fortunate coincidence in time, the work of preparing certain therapeutic standards, now required under the Act, has been facilitated by international agreements which have recently been reached under the auspices of the Health Section of the League of Nations. The second of two International Conferences upon the standardisation of biological products was held in Geneva early in September, 1925, when Great Britain, France, Germany, the United States, and five other nations were represented by distinguished pharmacologists. Unanimous international agreement was reached with regard to the standards to be adopted for such widely used and important substances as pituitary extract, insulin, thyroid gland, salvarsan, digitalis, and some remedies against parasitic worms. Valuable discussions took place and resultant arrangements for new work were made with respect to other substances in common use, but not yet susceptible of an agreed standardisation. The Council add that few international conferences in a field of such technical complexity and involving so many hitherto divergent national interests have reached within three days such felicitous agreement over a wide range of subjects, and attribute this happy result largely to the intellectual and personal qualities of Dr H. H. Dale, who acted as president of the conference.

(*To be continued.*)

## PARIS.

(From our own Correspondent.)

### *Tetanus Anatoxin.*

Ramon and Zoeller have just reported upon the effectiveness of tetanus anatoxin, which stimulates the formation of antibodies without being toxic. A series of some 170 injections showed that this method of vaccination is perfectly harmless, produces no local or general reactions, and effectually stimulates the formation of antibodies by the tissues Two injections may be given, at an interval of 25 days Ramon and Zoeller are continuing their studies on antitetanic vaccination

### *Proposed Insurance Legislation.*

A Bill has just been presented to the Senate for the compulsory insurance of wage-earners whose income does not exceed 12,000 francs annually, plus 2000 francs for every child Persons insured will pay 5 per cent. of their wages, and employers will contribute an equal amount The insurance is to provide against sickness, premature disability, unavoidable unemployment, medical and hospital care, old age, and the like For pregnancy and childbirth it will cover the period of gestation and six months following accouchement, and will provide a daily indemnity extending for six weeks before and six weeks after childbirth. Insurance will cease to be obligatory at the age of 60 years, with possible prolongation to the age of 65. The worker will be assured of an old age pension after continuing his 5 per cent payments for 30 years, and this pension will supply a sum equal to at least 40 per cent of the average income earned during the ten years preceding the age of 60. Proportional pensions will be awarded after an employment period of 25 years, and during forced unemployment the daily allowance will equal at least 40 per cent. of the usual wages.

This Bill considers medical relations more fairly than did an earlier draft, but it does not clarify the position of doctors as regards professional secrecy, and it is criticised on the ground that it does not provide for certain classes of workers It is unlikely to pass without further amendment.

### *An Antitoxin against Cancer.*

Maurice Bloch has presented 12 cases of cancer, including sarcomatous tumours, which have been cured or satisfactorily arrested by inoculating the patients with an antitoxin obtained from tumour cells in a state of fatty degeneration. The fatty tissue, which cannot be reproduced or act metastatically, is supposedly able to combat the toxins elaborated by cancers The treatment was suggested by cases in which lipoblasts were seemingly responsible for the spontaneous arrest and cure of sarcoma and carcinoma.

### *Prognosis of Cancer of the Stomach.*

From the results of 100 gastrectomies done by him during the last four years, Dr. Victor Pauchet, of Paris, has come to the conclusion that the presence of free hydrochloric acid in the gastric juice is a prognostic sign of great importance. Of 21 cases in which the acid was still present all but two recovered from the operation. Twelve of these have been since under observation and only two of them have relapsed rapidly in the first two years. In those with achlorhydria, on the other hand, the operative mortality was 22 out of 50. Thirteen are still under observation and six of these have relapsed rapidly. He sums up the situation by saying that in cases in which acid is present the mortality of operation is moderate, relapses are late, and the ultimate results are favourable In this connexion it is interesting to note the recent death, from pulmonary congestion, of a man of about 70 who was operated upon for cancer of the stomach by Tuffier in 1808. The growth was then found on examination to be an epithelioma of the tubulo-racemiform variety. Prof Hartmann has quoted similar cases and estimates that 30 per cent of patients in whom gastrectomy is done remain quite free from recurrence.

### *Recrudescence of Alcoholism.*

Several recent communications have called the attention of the Académie de Médecine to an increase in the number of cases of alcoholism. Prof. Jean Lépine, of Lyons, draws particular attention to the evil results of wine drinking, whilst Dr. Cazeneuve (of the same city) insists on the bad effects of alcohol in all its forms. Especially he condemns the aniseed-flavoured apéritif and, above all, the substitutes for absinthe, which are becoming more and more popular. These beverages are forbidden by law, but actually they are advertised in the most flagrant way. They seem entirely to escape the control of the authorities, whose powers to suppress fraud are quite inadequate. An increase in the number of alcoholic patients in the lunatic asylums of the Rhône coincides with the increase in the consumption of liquor.

### *Free Hospitals and Foreigners.*

An energetic campaign against the abuse of free hospital service in Paris is being waged by the French press, especially by the *Matin*. Gratuitous treatment and maintenance of undesirable foreigners throws a heavy strain on French finances, and the annual cost of free care of foreigners is estimated at 8 million to 10 million francs. At Paris 10 per cent. and at Lyons 13 per cent. of the children admitted to hospital are foreign, whilst at the Tenon Hospital 65 of 100 helpless tuberculous patients are foreign. During last year 275,000 foreigners were registered as arriving in France and probably 30,000 more entered the country without passports. This influx of undesirables not only burdens France and her taxpayers financially, but brings in trachoma, leprosy, and other epidemic diseases, and it seems likely that the campaign now on foot will result in legislation.

### *Lesions Produced Electrically.*

At the meeting of the Académie des Sciences on Dec. 7th last Dr. Jellinek discussed the great differences between cutaneous and organic lesions due to electricity and those which are the result of simple burns. Severe lesions caused by electric current heal by aseptic necrosis; fever and alterations in the general condition occur but rarely. Amputations, he considers, are often done unnecessarily; conservative treatment is generally successful, even in the gravest cases. The prognosis in electrical lesions is usually favourable; not only do the skin lesions heal, but recovery tends to occur in the nerves and spinal cord when changes have been produced in them.

Prof. Achard, secretary-general to the Académie de Médecine, is leaving France for several months on a mission to Japan, which he is undertaking at the request of the Ministry for Foreign Affairs. He will carry to the Japanese medical profession the cordial greetings of their French colleagues and will consider how the two countries may be brought into more intimate intellectual relations. The French Government, desirous as it was that a doctor should visit the Japanese so as to encourage the spread of French science, could not have made a better choice.

Prof. Gosset, known internationally as a brilliant surgeon, has been named Grand Officer of the Legion of Honour.

Owing to the noticeable incidence of small-pox among civilians in various parts of France, the Minister of War has circularised the generals of the French army, insisting on special strictness in the vaccination and revaccination of recruits.

In Paris the new regulation closing pharmacies on Sundays and holidays is being strictly enforced; one pharmacy is maintained open for each arrondissement. A number of pharmacists who have kept their shops open in spite of the prefect's decree have recently been fined by the decision of the Cour de Cassation (supreme court), which reversed a previous acquittal.

(FROM OUR OWN CORRESPONDENT.)

### *Professional Secrecy.*

THE German Criminal Code provides that medical men, as well as midwives, lawyers, and members of similar professions, are liable to punishment if, without being authorised to do so, they divulge facts with which they have become acquainted in the exercise of their profession. The maximum penalty is three months' imprisonment and a fine not exceeding M.1500 (£75). The term unauthorised—unbefugt—is essential. Even as a witness, according to the existing law, a medical man must decline to give evidence without the express authorisation of his patient, and when he is asked by an insurance company to give a certificate he is obliged to get the consent of the patient before complying with the request. In certain instances, however, a medical man may be obliged to act apparently against the principle of professional secrecy. It is quite evident that in notifiable diseases he must make the necessary declaration to the sanitary authority even in the face of the patient's objections, and this is not, of course, regarded as an unauthorised action but as one expressly authorised by the laws relating to infectious diseases. A medical officer to a school must also, as part of his duty, notify the school authority of the fact that a child is suffering from tuberculosis. But some situations are more doubtful. In a case in which a medical man informed the Government that one of his patients, who was in Government employ, showed signs of insanity, the Supreme Court decided that he was authorised to do so in the public interest, which must always have priority over the interest of the individual. It has also been decided that a doctor may, if necessary, disclose to the prospective father-in-law of one of his patients the fact that his patient is suffering from venereal disease. The Criminal Reform Bill, however, regulates the matter on a different basis. Hitherto a professional secret has been imposed only upon medical men, but the new Bill provides that everybody attending patients for money, even if not qualified, must observe the rules of professional secrecy. The medical attendant has to consider whether it may be in the public or private interest to divulge a fact of which he has become aware in his professional capacity, and in consequence the responsibility lies with the individual medical man. But even if a court concludes that he was wrong in divulging professional secrets he is not liable to be punished so long as he has done it after conscientious consideration of the pros and cons.

### *Frambœsia in the Dutch Indies.*

In a recent lecture Dr. Winckel, of Java, described the results obtained with salvarsan in the treatment of frambœsia. The disease affects only half-castes and natives but never Europeans, and prevails in nearly all tropical countries; in some places 90 per cent. of the inhabitants are infected. In a campaign against the infection a quantity of 500 kg. of neosalvarsan was imported to the Dutch East Indies by the Government and 1,600,000 injections were performed. The symptoms usually disappear soon after the first injection, but for a definite cure three or four injections are necessary. In certain districts the disease is rapidly disappearing, but it will take a couple of years to destroy it throughout the Dutch Indies, which have 45 million inhabitants. The Government has had practically no expenses as the cure is very popular among the natives and they willingly pay for the drug, the syringe, and cannulas. Dr. Winckel has approached the Hygienic Committee of the League of Nations suggesting international measures for the destruction of the disease.

### *The Genesis of Fæcal Concretions.*

Before the Berlin Medical Society Prof. J. Pick read a paper on the genesis of fæcal concretion in the appendix. He has examined 500 specimens of fæcal concretions and has found that in 170 of them the nucleus was formed of hair In 14 of them there was hair in the appendix without a concretion. The number of other foreign bodies found in the appendix was relatively small; 80 per cent. of the hair found was human in origin; 10 per cent. was derived from animals, and ½ per cent. from tooth-brushes. In the remainder the exact class could not be ascertained; 50 per cent. of all the concretions occurred in children up to six years of age, whilst concretions were found in 80 per cent. of cases of appendicitis in men and in 20 per cent. of women.

### *Distemper and Influenza.*

Before the Veterinary Society Dr Kantorowitsch lately read a paper on the connexion between distemper and influenza. The diseases, he said, are very similar. Both are spread epidemically and pandemically; the ætiology of neither has yet been ascertained, and they both produce symptoms of an obstinate character in the central nervous system. Together with Dr. Levy and Dr Kuczinski, of the Pathological Institute, he has carried out microscopical investigations in dogs which died from distemper. In the brains of 22 dogs in which there had been cerebral symptoms he found a protozoon identical with that discovered at the Stockholm Biological Institute in people who had died from encephalitis lethargica. He has observed that in cases of distemper the proprietors of the dogs have often been suffering from influenza, and suggests that the dogs may possibly have swallowed the virus in the sputum of their masters. It has never been observed, however, that distemper is conveyed to the human species. Inoculation with the Swedish virus and the distemper virus gave nearly identical symptoms, so that at least a near relation between the two viruses seems likely.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *The School of Physic, Trinity College.*

THE 200th anniversary of the organisation of the School of Physic in Trinity College was celebrated publicly in 1912 Last week the College held a domestic celebration of the 100th anniversary of the opening of the Medical School Buildings, and Dr. T P. C. Kirkpatrick delivered a lecture in the Theatre of Anatomy on the History of the School of Physic Having recounted the vicissitudes of the School in the eighteenth century, he dealt in detail with the life of James Macartney. This great teacher and organiser was born in Armagh in 1770, and studied anatomy under Hartigan in the school of the College of Surgeons. Moving to London, he was appointed lecturer in comparative anatomy at St. Bartholomew's, where he won a brilliant reputation. In 1813 he was elected professor of anatomy and chirurgery in the School of Physic, and his election produced remarkable changes. An untiring worker, his energy irradiated the entire school. In seven years his class rose from 53 students to 303, and it became impossible to find room for them in the old Anatomy House A new building had to be put up, and eventually the board consented to erect one on "the ground heretofore the bowling green." In its choice of site the board was probably influenced by a desire to keep the school buildings as far as possible from the rest of the college. Macartney appears to have been of rather hasty temper, for in an altercation with the architect he broke his umbrella on the architect's back. In spite of interruptions the building was finished, and on Nov. 1st, 1825, he delivered his inaugural lecture. Until the end Macartney maintained his supremacy, but his desire to rule the School brought about his fall eventually and he resigned in 1837. In the years that followed many great names were connected with the School William Stokes held the post of Regius Professor of Physic from 1840 till his death in 1878. Robert James Graves, whose name was so closely linked with that of Stokes, was King's Professor of the Institute of Medicine from 1827 to 1841, and was, perhaps, the greatest figure in Irish medicine. Other notable teachers were William Featherston-Haugh Montgomery, Robert William Smith, Robert Adams, Thomas Brady, Robert Travers, and Robert Law. In 1874 John Mallet Purser was elected King's Professor, and at once began to lecture, not on medicine, but on physiology. In addition, he gave lectures on practical histology. These lectures became popular, and in 1870 the board authorised an expenditure of £2700 for the building of a laboratory for histology and physiology. Here was started that splendid instruction in practical pathology which was given by Dr. Purser every year till 1895, when Alexander O'Sullivan was appointed lecturer in pathology and the laboratory of pathology was built at the cost of £6000 Dr. Purser continued as King's Professor of the Institutes till 1901, and in 1917 he was elected Regius Professor of Physic. To Prof. Purser's energy and ability as a teacher, as Dr. Kirkpatrick remarked, the success of the school in later years has been in no small measure due.

### *Deplorable Salaries in Co. Mayo.*

A serious position is arising in Co. Mayo owing to the failure of the County Board of Health to deal with the question of the salaries of their medical officers. Before the Board of Health took over the health administration of the county from the pre-existing unions a few years ago, scales of salaries had been adopted in some unions and not in others. There was no unity in the scales adopted, and some were more liberal than others. The Board of Health took over the scales as they existed, with the result that there is a complete lack of system in the salaries at present paid Some salaries rise by scale to a maximum of £250 or £300 a year, whilst others only reach £140 One medical officer has an unchanging salary of £100 During the past few years the Board of Health has been repeatedly asked to adopt a scale of salaries for the whole county, but so far no notice has been taken of the requests. The inadequacy of the salaries is all the more distressing in that in the greater part of Co Mayo there are little or no opportunities for private practice, and the medical officers are almost dependent on their Poor-law salaries. The medical officers have now put forward the demand that a scale equal to that in force in the neighbouring county of Galway should be adopted for Mayo. As the opportunities for private practice are better in the greater part of Galway than in Mayo, the demand is reasonable. In Galway the commencing salary is £250, rising by annual increments of £5 to a maximum of £300. If even such a modest scale were adopted in Co. Mayo it would mean an immediate increase of salary for every single medical officer in the county. Such a change would entail an increase in the rates of 2·1*d.* in the pound. Unless a speedy redress is given to the grievances of the medical officers there is a possibility of a general refusal to work.

### *The Irish Register.*

It was announced in Dublin on Jan. 18th that the Free State Government proposes to introduce legislation next month to extend the existing arrangements with the General Medical Council for a further period of six months.

---

LIVERPOOL HEART HOSPITAL.—Appreciation of the importance of preventive treatment in heart disease has led to the establishment of a new institution designed especially to provide accommodation for prolonged treatment in bed for rheumatic and other conditions liable to produce cardiac lesions. A house at 31, Oxford-street, Liverpool, has been purchased and suitably equipped for the purpose. Two wards have been opened, as well as some single bedrooms, and the premises will be extended as soon as funds are forthcoming. An electrocardiograph has been installed. Dr I. Harris has been elected hon. physician and Dr Noel Chamberlain hon. assistant physician to the hospital, and with them is associated a number of distinguished members of the profession in a consultative or specialist capacity.

# Public Health Services.

## MENTAL HOSPITAL REPORTS.

THE *West Riding Mental Hospital* at *Wakefield* has just published its 105th report. Among the 2000 patients the death-rate was 9·04 per cent. for males and 8 per cent. for females, and the recovery rate 24. The recovery among females was much higher than among males, the analysed figures being 16·5 and 32·6 respectively. This is partly accounted for by the large proportion of general paralytics admitted, 14 per cent. of the male admissions being sufferers from this incurable condition, while senile decay accounted for 30 per cent. of the 190 cases which came to autopsy. Much renovation and general repairs have been carried out during the year, including a new motor garage and permanent marquee shelters in six of the wards. The recreation hall has been largely reroofed and a fireproof cinematograph projecting box erected. Many more improvements are still needed, however, in the words of the medical superintendent, "to transform what has in reality been an antiquated prison into a healthy and comfortable hospital." There are far fewer juvenile admissions than there used to be, although suitable treatment is not yet provided elsewhere for these cases, so that many types of mental disease fall between the Lunacy Act and the Mental Deficiency Act and so get but poor attention. The special school, Stanley Hall, has now 28 boys, and the value of the rugs, baskets, stockings, and other articles made by these children was nearly £40 last year. The pathological laboratory has undertaken a good deal of routine investigation and much histological work for teaching and research. Four cases of dysentery were detected during 1924, two of which had probably contracted the disease before admission. The training in practical nursing is now in the hands of a hospital-trained deputy chief nurse, and 15 men and 8 women passed the preliminary examination for the medico-psychological certificate; 36 of the staff now hold the final certificate.

The *Bucks County Mental Hospital* at *Aylesbury* had 670 patients in residence on Dec. 31st, 1924, of whom 468 were usefully employed. Ample provision is made for recreation and the fortnightly cinematograph entertainments and the wireless installation have been greatly appreciated. Parole and money grants have been given in a number of cases and are seldom abused. The recovery rate was 36·2 per cent. The death-rate was 11·2 per cent., an average figure attained as the result of an abnormally high male death-rate (18·6) and a low female rate (5·4)—the lowest for many years. Nine men died from influenza, which was epidemic in the spring. An electric cooking and baking apparatus has been installed, comprising four roasting ovens, two stock-pots of 20 gallons capacity, an egg-boiler for 80 eggs, a boiling table, fish range, grill, four hot cupboards with sliding doors, and two baking ovens to deal with 1000 lb. of bread in five to six hours. The newly appointed dental surgeon visits weekly. The visiting commissioner comments on the number of senile female patients and the necessity for accommodating such cases in infirmary wards, also on the presence of a few juvenile cases who would be better in mental deficiency institutions. With the aid of the chairman's generosity the needs of certain patients for spectacles are being attended to.

The report of the *Inverness District Asylum* shows a slight increase in the number of cases under care, the average number for the year being 674. The recovery rate was 23·5 per cent. and the death-rate 4·7 per cent., a very low figure compared with either previous records of this institution or with the general rate for Scottish asylums. Only one of the deaths was due to pulmonary tubercle, and one more to typhoid, of which there was a restricted outbreak in the summer. No definite cause could be traced. Increasing interest is being taken in the football matches, 18 of which were played during the last season, while the cricket team won five of its 11 matches. As yet there is only one voluntary inmate in this hospital. During the year ten nurses and two attendants passed the final examination for their certificate, two with distinction.

The county of *Hampshire* maintains two mental hospitals. That at *Knowle* had just under 1000 patients resident at the close of the year 1924–25, the number of admissions having fallen markedly during the last two years. The recovery rate was 48·1 per cent. and the death-rate 8·4, both figures showing distinct improvement on previous records. Post-mortem examinations were held on 75 per cent. of the fatal cases. The general health of the patients is showing steady improvement, particularly in respect of colitis, of which there were only five mild cases during the year, instead of an average of 74 for the years 1918–22. For this the new dietary arrangements instituted since the report of the departmental committee and the appointment, two years ago, of a visiting dentist, may be held largely responsible. The investigation of the nine cases of typhoid revealed eight carriers, which should lessen the future incidence. The tuberculosis rate remains the same. The newly installed cinematograph and wireless set have given much pleasure. The patients are encouraged to work about the hospital grounds and in the various shops and workrooms, and many useful articles have been made, particularly in the new basket-making department. Parole is extensively used. One ward is being reconstructed for the malarial treatment of general paralysis. Eleven attendants and four nurses obtained their certificate. The admission rate at *Park Prewett* has gone up and there were 1140 patients in residence at the end of the year. The recovery rate was 23·5 per cent. and the death-rate 6·96 per cent. The health of the patients was satisfactory and there were no epidemics. The hospital has wireless and cinematograph sets, and three detached blocks are used exclusively by patients on parole. A lady gardener has been appointed to supervise the women patients who can benefit from garden and poultry-farm work, while others are employed in the workshops and about the building. An automatic electrically-controlled continuous bath has been fitted up. Nine male and five female nurses obtained their certificate, bringing the total to 12 and 11 respectively.

The *Stirling District Board of Control* has over 800 patients in its institution at *Larbert*, including three voluntary boarders. The recovery rate for the year 1924–25 was 41·7 per cent., in spite of the fact that 46 per cent. of the admissions were incurables, 17 being senile cases, 16 general paralytics, and 15 mental defectives. Eighteen patients were sent out on probation during the year and only two returned as unsuitable. The death-rate was 11·4 per cent. and the cause was verified by post-mortem examination whenever permission could be obtained. There were no epidemics. Three cases of typhoid fever occurred, one of them in an advancing case of general paralysis. After the fever he was so greatly improved that he was able to return home and engage in his former employment quite satisfactorily. The farm is a most successful part of the institution, both financially and therapeutically, and it has been extended by the purchase of an estate of over 900 acres. It is hoped to establish a colony for mental defectives on this new estate, a most desirable procedure and one for which the need is pressing. It is now assumed that all nurses will take the M.P.A. certificate and they are not placed on the permanent list until the preliminary examination is passed. During the year nine nurses and eight attendants obtained thei certificate. This is one of the institutions provided with a "tuckshop," much appreciated by the patients.

The *East Sussex County Mental Hospital* at *Hellingly* is one of the many mental hospitals which are overcrowded. It has 1165 patients, a slight increase on the previous year. The recovery rate was 41, and the death-rate 7 8 per cent. Seventy patients were sent out in the course of the year on trial, 36 with a money grant of 15s. per week. Only six relapsed. A severe epidemic of influenza attacked patients and staff in the spring. Sporadic cases of scarlet fever and paratyphoid B also occurred, but dysentery has been considerably reduced. Antidysenteric serum has become the routine treatment. General paralytics had been treated by malaria for a few months only before the publication of the report. The physical drill classes for female patients have been very successful, both mentally and physically. Verandahs are to be erected and a new and excellent water-supply has been provided on the estate. A new operating theatre is to be provided; last year the visiting surgeons performed over 20 operations in an ordinary ward. An ophthalmic surgeon has been appointed and saw 300 cases during the year, while 757 attendances were made at the dental sessions. In many cases where septic conditions in the mouth have been rectified, considerable improvement has taken place in the mental and general health. About 50 per cent. of the patients are usefully employed. The laboratory has been thoroughly equipped and a pathologist appointed: he has been largely occupied with the investigation of dysentery, and points out that so long as open bucket latrines remain in the patients' courts cases of dysentery are bound to occur. The pass-lists in the nurses' examination for their certificate have improved since the appointment of a sister tutor, but, like so many other mental institutions, Hellingly finds it exceedingly difficult to find suitable female candidates.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 9TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 235 (last week 203); scarlet fever, 1750; diphtheria, 1012; enteric fever, 43; pneumonia, 1761; puerperal fever, 60; cerebro-spinal fever, 7; acute poliomyelitis, 4; acute polio-encephalitis, 2; encephalitis lethargica, 55; dysentery, 6; ophthalmia neonatorum, 114. There were no cases of cholera, plague, or typhus notified during the week.

Of the 235 cases of small pox, 25 (last week 21) were reported from the county of Derby; 110 (last week 90) from the county of Durham, now widely scattered over boroughs, urban and rural districts; 11 each from the counties of Northumberland and Nottingham; 1 from the East Riding of Yorkshire (Kingston-upon-Hull); and 67 from the West Riding, 58 of which (last week 48) occurred in Rawmarsh.

*Deaths.*—In the aggregate of great towns, including London, there were 5 (1) deaths from enteric fever, none from small-pox, 72 (33) from measles, 16 (3) from scarlet fever, 30 (2) from whooping-cough, 53 (20) from diphtheria, 63 (17) from diarrhœa and enteritis under 2 years of age, and 111 (24) from influenza. The figures in parentheses give the numbers for London itself. The number of deaths from influenza is substantially less than last week—namely, 123 (27).

# The Services.

## SMALL-POX AREAS.

FLEET orders have been issued giving a recapitulation of the restrictions in regard to leave for officers and men proceeding to any town or district in which an outbreak of small pox has been notified. For the present these restrictions operate in Ashington U.D., Bedlingtonshire U.D. (Northumberland); Blackwell R.D. and Derby (Derbyshire); Blaydon U.D., Chester-le-Street U.D., Easington R.D., Gateshead, Houghton-le-Spring R.D., Lanchester R.D., Ryton U.D., and Sunderland R.D. (Durham); Hucknall U.D. and Sutton-in-Ashfield U.D. (Notts); Kingston upon-Hull, Middlesbrough, Rawmarsh U.D., and Sheffield (Yorkshire).

## ROYAL NAVAL MEDICAL SERVICE.

Surgeon Rear-Admiral J. F. Hall, C.M.G., has been appointed an Honorary Surgeon to the King in place of the late Inspector General of Hospitals and Fleets, Sir Henry F. Norbury, K.C.B., K.H.S.

Surg.-Capt. W. L. Martin has joined the staff of the Royal Naval Hospital, Plymouth.

### ROYAL NAVAL VOLUNTEER RESERVE.

The King has approved of the award of the Royal Naval Volunteer Reserve Officers' Decoration to Surg. Cmdr. D. D. F. Macintyre.

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. R. N. Hunt, half-pay list, late R.A.M.C., retires on retd. pay on account of ill health.

Lt.-Col. J. H. Robinson retires on retd. pay.

### TERRITORIAL FORCE.

Lt.-Col. V. T. Carruthers (Maj., Res. of Off.) resigns his commn. in the T.A. Capt. F. G. Leacher to be Lt.-Col. and to command the 137th (North Midland) Field Ambulance.

## ROYAL AIR FORCE.

John D'Isney Rear is granted a short service commission as a Flying Officer for three years on the active list, and is seconded for employment at Royal Sea Bathing Hospital, Margate.

## INDIAN MEDICAL SERVICES.

The services of Maj. J. B. Hanafin, officiating director of public health, Assam, have been placed at the disposal of the Government of India. Maj. J. L. Sen, M.C., has been confirmed as a Civil Surgeon, Assam. Lt.-Col. F. L. Wilson officiates as Residency Surgeon and Chief Medical Officer, Baluchistan, vice Lt.-Col. L. J. M. Deas on leave. Maj. W. O. Walker has been appointed Civil Surgeon, Serampore. Lt.-Col. H. G. Stiles Webb has been reposted as Officiating Director of Public Health, Central Provinces. Lt.-Col. W. Davis to be Civil Medical Officer of Ranikhet, vice Maj. T. T. H. Robinson. The following have been granted leave: Maj. E. C. Doyle, acting Inspector-General of Prisons; Maj. E. S. Phipson, Health Officer, Port of Aden, and Medical Officer, European General Officer, Aden; Lt.-Col. W. O. S. Murphy, Director of Public Health, Government of Bombay; Lt. H. B. Rosair, Superintendent of Jails, Fatehgarh. Maj. B. F. M. Newland, civil surgeon, has been granted an extension of leave. Lt.-Col. W. R. Battye has been posted as Administrative Medical Officer, Central India, and Residency Surgeon, Indore, vice Lt.-Col. J. R. J. Tyrrel, granted leave. Lt.-Col. J. Cunningham, late Director King Institute, Guindy, has been appointed Director of the Pasteur Institute of India. Lt.-Cols. C. A. Sprawson, Principal, King George's Medical School, Lucknow, and J. Hunter, civil surgeon, Lucknow, have been appointed members of the United Provinces Medical Council, vice Maj. G. J. Burke and Lt.-Col. Hugh C. Buckley. Lt.-Col. G. Tate, Officiating Inspector-General of Civil Hospitals, Punjab, has been appointed Principal and Professor of Surgery, King Edward Medical College, Lahore, vice Lt.-Col. H. H. Boone, granted leave. Capt. S. W. Hayes, civil surgeon, Dalhousie, has been appointed Professor of Operative Surgery, King Edward Medical College, Lahore. Capt. G. E. L. Simons acts for him. Lt.-Col. W. D. Ritchie, civil surgeon, Darrang, has taken over charge of Jagpur Jail from Maj. J. F. James. The following have been granted leave: Lt.-Col. J. G. N. Stokes, Director of Public Health, United Provinces; Lt.-Col. W. J. Powell, Inspector-General of Prisons, Central Provinces. Maj. H. H. King, Director of the Pasteur Institute of India, officiates as Director of the King Institute of Preventive Medicine, Guindy, Madras. Lt.-Col. C. L. Dun, Director of Public Health, United Provinces, has been appointed a member of the United Provinces State Board of Medical Examination, vice Maj. W. A. Mearns, resigned. Lt.-Col. J. W. D. Megaw, Principal, Calcutta School of Tropical Medicine and Hygiene, has been appointed Honorary Surgeon to the Viceroy, vice Col. R. P. Wilson, late Acting Surgeon-General with the Government of Bengal. Maj. P. M. Rennie, civil surgeon, has been appointed to the executive and medical charge of the District Jail, Hoshangabad.

Dr. H. W. Gush, senior medical officer, West African Medical Staff, has been appointed to be a surgical specialist in the Gold Coast.

---

**GLASGOW ROYAL INFIRMARY.**—The annual report states that the managers are *considering* preliminary steps towards the establishment of a new biochemical department, and that the Muirhead trustees have enabled them to establish two post-graduate research scholarships for medical women of £100 each, tenable for a year, and renewable at the option of the trustees. There were nearly 11,000 in-patients, an increase of 1200 on the previous year, and nearly 52,000 out-patients, an increase of 3261. The ordinary expenditure was £110,000, and the year's deficit £25,000.

"Audi alteram partem."

## ACUTE HÆMORRHAGIC NEPHRITIS.

*To the Editor of* THE LANCET.

SIR,—The interesting study of acute hæmorrhagic nephritis in children by Dr. W. G. Wyllie and Dr. A. Moncrieff which you publish this week, brings to notice an aspect of nephritis which has been overlooked by many writers on renal disease. Several years ago my attention was drawn to the occurrence of severe grades of hæmaturia in the course of what could be regarded clinically as nothing else than subacute or chronic parenchymatous nephritis—to use the classification of nephritis commonly accepted in this country. Since that time I have observed 17 examples of the condition, all the patients being in the clinic of my chief, Prof. W. K. Hunter, at the Glasgow Royal Infirmary. I hope to publish the records of these cases shortly, but a brief reference to them may be of present interest in connexion with the paper by Dr. Wyllie and Dr. Moncrieff.

My cases have a general resemblance to those which they describe, but differ from them in that (with two exceptions) the patients were all young adults. Excluding one patient 8 years old and another 54 years old, the ages ranged from 15 to 40, and most of the patients were between 15 and 30 years of age. The hæmaturia was often very copious and in many instances it persisted over periods of weeks or months with only occasional intermissions. The longest continuous record of hæmaturia in the series extends over 18 months, but there were other cases in which the bleeding had not ceased on dismissal from hospital.

That abundant blood in the urine is by no means a rare symptom in nephritis is shown by the fact that in a series of 100 consecutive cases of nephritis of all types admitted to Prof. Hunter's wards I found the following incidence of hæmaturia: No hæmaturia 44, hæmaturia lasting not more than seven days after admission 19, hæmaturia lasting eight days or more 37 cases. Further analysis shows that of the 37 cases with persistent hæmaturia some were examples of acute nephritis (primary attacks of exacerbations of a previous nephritis) and some were examples of chronic interstitial nephritis. There remained, however, 14 cases in which the nephritis was of either the subacute or the chronic parenchymatous variety. I doubt if this form of hæmorrhagic nephritis can be regarded as identical with that described as occurring in children by Dr. Wyllie and Dr. Moncrieff, in spite of many points of similarity between their cases and those which I have seen. Apart from the age-incidence, there are other differences. Thus, I can find nothing in the latter series of cases to suggest any infective or septic ætiological factor such as is suggested by your contributors. It is, perhaps, merely a coincidence that the case in my series which most closely resembled theirs in its earlier stages was the only one which proved fatal. This patient was a boy, aged 8 years, whose first symptom was profuse hæmaturia, and who had blood in his urine almost continuously till his death from uræmia a year and a half later.

Dr. Wyllie and Dr. Moncrieff make reference to the possibility of there being quantitative alterations in the blood proteins in such cases. It may interest them to have the following data in this connexion. From the results of such estimations in seven samples of plasma from four of my cases (using Wu's method) I found: Total proteins, maximum = 8·500 per cent.; minimum = 4·808 per cent.; mean = 6·431 per cent. Albumin, maximum = 4·946 per cent.; minimum = 2·720 per cent.; mean = 4·031 per cent. Globulin, maximum = 3·377 per cent.; minimum = 0·170 per cent.; mean = 2·080 per cent. Fibrinogen, maximum = 0·385 per cent.; minimum = 0·187 per cent., mean = 0·293 per cent. I do not wish to comment upon these results further than to say that while the mean values indicate a slight relative decrease of albumin and a slight relative increase of the globulin fraction (as judged by the normal cases recorded by Wu (1922)), my experience of such estimations of the plasma proteins is that the results show ranges of variation, even in normal cases, so great that it is unwise to attempt to draw conclusions from the examination of small series of cases. With regard to the other chemical features of these cases of hæmorrhagic nephritis it may be said briefly that there was in *most* patients no indication of gross nitrogen retention—the blood-urea and non-protein nitrogen being normal or only slightly above normal, and the response to the urea-concentration test being usually satisfactory.

So far I have not been able to find any adequate explanation of the mechanism by which the bleeding is produced in this form of nephritis, but I feel as sure as one can be without histological evidence that the bleeding is not due to congestion alone. One is tempted to try to find analogies between this form of nephritis and such hæmorrhagic conditions as the purpuras, but I have never found any gross reduction in the number of blood platelets such as occurs in the latter.—I am, Sir, yours faithfully,

J. N. CRUICKSHANK, M.D., F.R.F.P.S. Glasg., M.R.C.P. Lond.,
First Assistant to the Muirhead Professor of Medicine Glasgow University; Director, Research Department, Glasgow Royal Maternity and Women's Hospital.

Jan. 16th, 1926.

## INTRA-URETHRAL NEGATIVE PRESSURE DURING COITUS.

*To the Editor of* THE LANCET.

SIR,—An argument is occasionally put forward by those who are sceptical regarding the efficacy of immediate self-disinfection as a means of preventing gonorrhœa, to the effect that during the act of coitus a suction action is produced whereby infective matter is carried down the male urethra beyond the reach of disinfectants applied with a swab or sponge. I am unable to trace this argument as having been brought forward by any witness before the Committee of Inquiry, presided over by Lord Trevethin, although it is recorded in the report, published in 1921, of the Venereal Disease Committee organised by the National Birth-Rate Commission. On page 3, Part II., of this report, Mr. Charles Gibbs, F.R.C.S., is reported to have said:—

> "One can understand that in large military areas where you have excellent doctors who are drilling and teaching the men how to use it (the prophylactic packet) one can understand that after some time one would get good results; but for the ordinary public to say 'get up in a corner and wash the penis in permanganate of potash' is useless. The danger time is the time of intercourse. The shape of the male organ is such that the orifice of the glans penis opens in the introducing movement and closes in the withdrawing action *thus sucking infection into the urethra* [my italics], and I do not think it will have any effect to apply disinfectant on the outside in many cases."

No one will deny Mr. Gibbs's statement that the meatus "opens in the introducing movement and closes in the withdrawing action," but his deduction "thus sucking infection into the urethra" cannot be so easily accepted. On the contrary, I believe that the closure of the meatus during the withdrawal action prevents the possibility of suction of vaginal fluids into the male urethra, the lips of the meatus acting as a valve and closing *immediately* the withdrawal action commences, and acting as a valve closing the more firmly the more vigorous the withdrawing action.

It is possible that a negative pressure or suction action may be produced in the *vagina* on every withdrawal stroke, the vagina being the cylinder and the penis the piston, but such suction action in the vagina would tend to *prevent* the entrance of infective matter into the male urethra rather than to encourage it. If Mr. Gibbs's suction theory was based on an erroneous interpretation of the mechanical processes taking place in the penis and vagina during coitus, then it necessarily follows that all argument founded on such false premises falls to the ground.

I am, Sir, yours faithfully,
Jan 18th, 1926. H. WANSEY BAYLY.

*** We need more material on which to base opinions as to the value of prophylaxis, especially as to how quickly organisms placed on the meatus spread up the urethra.—ED. L.

## THE TREATMENT OF HUMAN ANTHRAX.

*To the Editor of* THE LANCET.

SIR,—In your issue of Jan. 0th Dr. A. Pijper, of Pretoria, warmly recommends the salvarsan treatment of human anthrax. Some years ago a man with 12–15 sores distributed over the body came to me for treatment. Smears were taken from several vesicles and the anthrax bacillus was found in each. The sores were frozen with ethyl chloride, the centres scooped out and touched with carbolic acid, and 1/100 sol. carbolic acid injected into the surrounding tissues. The sores varied from some with blackened centre and œdema of tissue to small hard lumps almost cartilaginous when cut out. The patient made a good and painless recovery. Three weeks before he had buried a cow that died of an unknown disease. This case helped to show that cutaneous anthrax can be controlled in various ways, and I wonder if there is any record of pulmonary anthrax having been successfully treated by neosalvarsan.

I am, Sir, yours faithfully,
Cowes, Isle of Wight, Jan 17th, 1926. L. P. GIBSON.

## INSTRUMENTAL MIDWIFERY.

*To the Editor of* THE LANCET.

SIR,—Many years ago I was summoned to appear before the Master of Rotunda to explain why, when attending confinements outside the hospital, I never took to the case a midwifery bag. The reply was that "I did not think it was necessary." Next, I was asked to explain in detail how I conducted an ordinary confinement? The answer was, "I inquire when the labour commenced; count the woman's pulse, note the character of the pains, disinfect my hands in a strong solution of biniodide of mercury, palpate the abdomen, examine over the sacrum for œdema, and listen to the fœtal heart. Here is what I use in lieu of a midwifery bag," and produced from my waistcoat pocket a large pill-box containing biniodide of mercury tabloids. "My cases never show pyrexia during the puerperium, as I seldom find it necessary to examine P.V." The Master handed me a short list of articles to take to every confinement that in future I attended.

On my way back to the residents' quarters I met a doctor from the State of Illinois to whom I told my troubles, that I was on duty that day and could not comply with the Master's orders. He kindly offered to lend me the few articles which appeared on the Master's list and took me to his cubicle for this purpose. His instruments were truly wonderful; he seemed to possess everything that any surgeon could want under any circumstances. Leaving him, uneasy in my mind, I was guilty of a discourteous act for which I have ever since been secretly ashamed—I went and examined the out-patients' case book and found that *nearly all his patients were running temperatures.* Since those days, like many others, I have spent very many sleepless nights—waiting for infants to be born naturally. The counterfoils of my death certificate book are still without a maternal blemish. I believe this result has been accomplished on the idealistic lines expressed by Prof. Ranken Lyle at the meeting of the Edinburgh Obstetrical Society reported in your last issue. I am convinced that careful antenatal care with induction in certain cases when the child is viable will meet many cases which, allowed to drift, lead to Cæsarean section or craniotomy.

Someday midwifery forceps may be of historical interest only. Prof. Lyle's idealism is easier to attain than casual observation might lead one to believe. It certainly should not be possible to quote statistics embodying thousands of cases of craniotomy and Cæsarean section. Suppose for one instant that on opening your morning newspaper it announced the number of infants delivered by forceps in the British Isles in the preceding 24 hours! Are forceps *really* necessary as frequently as they are used? The fact that patients arrive in labour at term at the maternity hospitals requiring urgent operations is irrefutable evidence that someone or other has failed to live up to Prof. Lyle's idealism. I do not know Prof. Lyle, but I think that he will agree with me that the way to reduce maternal mortality is to have a coroner's inquest on every woman who dies in childbirth and let the death be attributed to misadventure, make conception notifiable early, and let the principal work of the maternity hospital be the care of the expectant mother.—I am, Sir, yours faithfully,

J. HARGREAVES ROBINSON.
Harley-street, W., Jan. 18th, 1926.

## PROFESSIONAL CRITICISM OF THE GENERAL MEDICAL COUNCIL

*To the Editor of* THE LANCET.

SIR,—I am sorry to have misread Dr. Gordon Ward's meaning, and apologise to him for having done so. I am not sorry, however, that I wrote my previous letter, because as I misread Dr. Ward's meaning it is almost certain that others have done the same. The matter is of some importance, as I fear that there are officials of approved societies, and even members of insurance committees, who believe that doctors are capable of doing such things. Now there is need of amendment of the certification rules under the National Insurance Act and also of improvement in the ways in which these rules are interpreted and carried out by certain officials of some societies. It is difficult to say which of these is the greater need, but it is certain that the advance must come by mutual agreement between the officials of the societies who have to make payments under the Act, and the doctors who advise them, an end to which we are not likely to attain if there is any suspicion of one side by the other.—I am, Sir, yours faithfully,

Welbeck-street, W., Jan. 19th, 1926. T. B. LAYTON.

## GLYCOSURIA AND LIFE ASSURANCE.

*To the Editor of* THE LANCET.

SIR,—In your issue of Jan. 0th you comment on the attitude of life insurance companies towards clients whose urine is found to contain a copper-reducing substance, and suggest that they are not quite fairly dealt with. May I point out that you do not take into consideration the following important matters—namely, that owing to the apparent dislike of a section of the public to undergo medical examination—hence the growing popularity of the non-medical schemes—the applicant, if medically examined and found to be glycosuric, is often not prepared or willing to incur the expense or time involved in having his blood-sugar curve taken. It is surely no part of the duty of the company, even if the applicant is willing, to spend time and incur expense in conducting such investigation. In three cases lately examined where such investigation was carried out by the applicants, the blood-sugar indicated in one the probability of diabetes and in the other the practical certainty of it. Yet these cases might otherwise have been easily passed as ordinary risks under the non-medical schemes as everything else appeared normal.

I am, Sir, yours faithfully,
ARTHUR T. DAVIES, M.D., F.R.C.P.
*Tokenhouse Yard, London, E.C.*, Jan 11th, 1926.

# THE TWORT-D'HERELLE PHENOMENON.

*To the Editor of* THE LANCET.

SIR,—We should like to offer a few remarks on the so-called action of transmissible bacterial lysin on dead bacteria. In a recent number of THE LANCET[1] F. W. Twort reports the following experiment:—

> "A new strain of the lysable white micrococcus and fresh active lysin were obtained from vaccinia. The micrococcus was isolated free from lysin, and grown on agar slopes for 24 hours; from these a moderately turbid emulsion was made with normal saline. The emulsion was heated in a water-bath at 60° C. for one hour, then mixed with an equal quantity of ordinary sterile peptone-beef broth, and 2 c.cm. of the mixture pipetted into each of four sterile test-tubes. Tube 1 received no addition. Tube 2 was inoculated with a loopful of pure living micrococcus. Tube 3 was inoculated with two drops of filtered lysin. Tube 4 was inoculated with two drops of filtered lysin and a loopful of the living micrococcus. This experiment throughout the paper will be referred to as the standard experiment. The four tubes were incubated at 37° C. After 24 hours tubes 1 and 3 showed no visible change. Tube 2 showed an increase of turbidity, while tube 4 showed a marked clearing of the emulsion."

From these facts Twort infers that there is lysis of dead bacteria when the lytic agent is being freshly produced in the presence of living bacteria of the same variety. About two years ago we performed, with the same results, experiments entirely identical, and for a while we had the same opinion as Twort has since expressed. But a more complete analysis of the phenomenon afforded a quite different interpretation, as will be seen. Although our results have already been briefly reported,[2] it will be of interest to recall here the circumstances that led us to our investigations and to our conclusions. When to a tube of broth seeded with staphylococci an extremely small amount of filtered lysin is added, the growth is not inhibited and an apparently normal culture is obtained. A few days later, however, when there is no longer growth and the bacteria are at rest, or perhaps already degenerating, the culture gradually becomes completely clear. It is therefore evident that, contrary to the usual observations on the transmissible lysis of other bacteria—e.g., the colon bacillus—a bacterial lysis occurs, in this case in conditions where bacteria do not grow. We therefore hoped that in this particular instance we could perhaps obtain the lysis of dead micrococci as well.

*Experiment.*—From a 24-hour agar slant culture of staphylococci a suspension was made and thoroughly washed. Heated for one hour at 62° C., the suspension was then diluted in sterile broth until the opacity was equal to that of a broth culture of staphylococci, and then divided in a few sterile test-tubes, half of these tubes receiving no addition while to the others was added two drops of filtered lysin. After a week at room temperature the turbidity of the first tubes remained unchanged, while the second set of tubes showed a partial but quite striking clarification.

In this experiment, then, dead staphylococci were partially dissolved by the filtered lysin. The result was clear-cut, and because of its significance we reported it at once in a preliminary note at the Société de Biologie. We very soon regretted our haste. When repeating these experiments later on we obtained very irregular results. Sometimes mixtures of dead micrococci with filtered lysin showed a marked clarification, while in many other instances not the slightest clearing could be noted, even after several weeks. By plating these mixtures we were then aware that the unchanged mixtures were always perfectly sterile, while the clarified ones contained a few living staphylococci that had been introduced into the mixture either with an insufficiently heated suspension or with a filtered lysin which had been passed through an unsatisfactory filter. Accordingly, the following experiments were performed with carefully controlled suspensions of dead staphylococci and carefully controlled filtered lysin.

*Experiments.*—The broth suspension of dead staphylococci was pipetted into each of four sterile test-tubes. Tube 1 received two drops of sterile broth. Tube 2 received one drop of sterile broth and one drop of living culture of staphylococci. Tube 3 received one drop of sterile broth and one drop of filtered lysin. Tube 4 received one drop of filtered lysin and one drop of living culture of staphylococci. After three days in the incubator at 37° C. tubes 1, 2 and 3 remained turbid, tube 2 being sometimes even more turbid than the others; tube 4 showed a striking, although incomplete, clearing.

The filtered lysin alone is thus unable to dissolve dead bacteria, but when associated with living bacteria it brings about a marked clarification. Control experiments proved that such a result could only be obtained with bacteria of the same species. Experiments and conclusions were exactly the same as those recently reported by Twort. Our next step, however, taught us that our interpretation was erroneous.

*Experiment.*—The preceding or standard experiment was repeated in exactly the same way, except that instead of using broth suspensions of bacteria we used saline suspensions. After three days' incubation at 37° C. tubes 1 and 3 were unchanged, but tube 2 this time was exactly as clear as tube 4.

Therefore, when the process happens in saline, it becomes evident that it is not the lysin that dissolves the dead bacilli, it is the living bacteria that are responsible for it. In fact, the same thing occurs in broth; the living bacteria introduced in tube 2 dissolve the dead bacteria in broth as well as in saline, but in broth they multiply actively and conceal by the opacity of their own growth the clearing of the dead suspension. The presence of lysin, perfectly meaningless when the experiment is done in saline, plays merely a secondary rôle when in broth by preventing the growth of the living bacteria to mask the clarification they brought about.

That such is the real meaning of the preceding experiments would be thoroughly proved if we could obtain the same result in broth as in saline by preventing the growth of living bacteria by some other means. This was realised as follows: Since Jaumain's experiments[3] it is known that in sealed tubes—i.e., in confined areas—staphylococci do not grow.

*Experiment.*—In a gas flame, a stricture was made in the middle of four sterile test-tubes. The bottoms of these tubes were filled with broth suspension of dead staphylococci up to the stricture and then convenient amounts of filtered lysin and living bacteria were added according to the standard experiment. Immediately after the stricture was closed in the flame and the sealed tubes were incubated at 37° C. for three days. Tubes 1 and 3 remained turbid; tubes 2 and 4 were clear.

Exactly as in the saline experiment, the living bacteria in tube 2 dissolved the dead emulsion as well as in tube 4, but as they were unable to grow in the sealed tubes the clearing remained visible. If we now open the tube 2 and pipette aseptically the clarified mixture into an ordinary test-tube, after a few hours growth at 37° C., the living bacteria have multipled and, as in the standard experiment, mask the clearing of the dead organisms. Living bacteria alone dissolve the dead ones; the presence of the lysin in broth suspensions is necessary to prevent the growth of the living cocci which mask the clearing of the dead suspension, and is superfluous when the experiment is done in saline or in sealed tubes.

In further experiments we were able to demonstrate the dissolution of the dead cocci by the living ones not only in liquid suspensions but also on solid media. The temperature at which the bacteria were killed is indifferent. It is a nutrition phenomenon; the living bacteria multiply to some extent while the dead cocci are reduced to minute Gram-negative granules. It affords not only the real interpretation of the standard experiment but also an explanation of Jaumain's phenomenon—i.e., the spontaneous clearing of broth cultures of staphylococci in sealed tubes. It is easy to show that in a confined area most of the cocci very quickly die, while the few that remain alive dissolve the dead cocci. This mechanism of auto or isophagy is available also for the ordinary autolysis of bacteria. It is one of the aspects of the necessary destruction of dead bacteria on the earth, this being also realised to a great extent in nature by heterophagy One of us, with Sara Dath,[4] has recently studied the remarkable lytic action that different micro-organisms, and especially mould like streptothrix, exert on a great number of bacteria, a phenomenon which was also studied independently by R Lieske [5]

We conclude, therefore, that the dissolution of dead cocci observed in the recent experiments of Twort and in our former experiments, apparently due to the lytic agent, is, in fact, produced by the living cocci, the rôle of the lysin being only of a secondary importance by preventing the growth of the living bacteria from concealing the clearing they had brought about Up to the present time no evidence has been brought forward to indicate that the transmissible bacterial lysin or bacteriophage is able to dissolve dead bacteria. It is of importance because the dissolution of dead bacteria by the transmissible lysin would be a most significant fact for the understanding of the Twort-d'Herelle phenomenon

We are, Sir, yours faithfully,
André Gratia.
Bernice Rhodes.

## MEDICAL SERVICES TO INDUSTRIAL FIRMS

*To the Editor of* The Lancet

Sir,—May we bring to the notice of all medical practitioners specially interested in industrial medicine the recent formation of an association of British industrial physicians and surgeons under the title of the Council of Industrial Medicine" This body commenced its existence a year ago as the British Section of the International Medical Congress on Industrial Accidents and Diseases, which held its fourth meeting at Amsterdam in September last, and it has now been incorporated in the Federation of Medical and Allied Services. Its objects are to promote the study of this important branch of preventive medicine; to enable practitioners thus engaged to meet and discuss common problems, and to provide a source of information on industrial health questions. Already the medical officers of a number of the leading industrial firms in London and the provinces have joined the Council, but it is known that there are many practitioners similarly engaged whose names cannot readily be ascertained To all such full particulars will gladly be sent on receipt of a postcard addressed to the Secretary, Council of Industrial Medicine, Federation of Medical and Allied Services, 12, Stratford place, London, W 1

We are Sir, yours faithfully,
D A. Coles,
Chairman.
Edgar L. Collis,
Thomas Oliver,
Theodore Thompson,
Vice-Chairmen
N Howard Mummery,
Hon. Medical Director
H S. N Menko,
Hon Foreign Medical Secretary

Jan. 19th 1926

---

The late Dr. W P Hilliam—William Percy Hilliam, who died on Jan. 11th at his residence at Storr Hill Bradford Yorks studied at the Sheffield School of Medicine at Edinburgh and at St. Thomas's Hospital, London, qualifying L.S.A in 1803 He was an ardent and accomplished horseman, a keen sportsman, and an assiduous follower of the Fitzwilliam hounds. It is recorded that in 1881 when he was out with the hounds, his horse took fright and in bolting cleared a wagon and four horses making a distance of 38 feet from taking off to landing. Dr Hilliam leaves a widow and one son. Brigadier-General Edward Hilliam, who served with the Canadian Contingent, is his younger brother

# Obituary.

## GEORGE HERBERT HUNT, M D Oxf, F R.C.P Lond

The death, at the early age of 41, of Dr G H Hunt, physician to Guy's Hospital, which occurred on Jan 9th, has already been announced in The Lancet

George Herbert Hunt was educated at Rugby School and was in Mr Whitelaw's House He went up to Christ Church, Oxford, where he began to study medicine, taking second-class honours in the Final Honour School of Physiology in 1006 It was at Oxford that he carried out his first piece of research, namely, the testing of the nitrogen excretion in the urine of a perfectly healthy man immediately after the excision of one kidney, an operation necessitated by an accident at football; it was concluded that the other kidney at once took up adequately the complete excretory function. This was long before the days of blood urea estimations, so that any temporary retention could not be tested This, as so much else of Hunt's research work, was carried out in collaboration with others making it not always easy to separate out his particular contribution He was an absolutely unselfish worker, taking endless pains to do his part of the work efficiently

Dr G. H. Hunt

Hunt entered Guy's Hospital in 1907, where he early developed an exceptionally keen clinical faculty He held the appointments of clinical assistant, out patient officer and house physician, and was appointed medical registrar as soon as his time as house physician was completed Two years later, in 1913, he was appointed assistant physician and he became full physician to the hospital as recently as last summer In early days he was a little nervous about passing examinations, though he always sailed through with flying colours, in later life he lost this diffidence and became a first-rate physician and an excellent teacher In 1914 Hunt served in the 1/2 London Casualty Clearing Station in France, in 1916 at the No 25 General Hospital, B E.F, in 1916–17 at the Royal Military Hospital, Devonport, in 1917 at the Royal Victoria Hospital, Netley, and in 1917–19 at Cambridge, where he worked in close coöperation with the R.E Experimental Station, Porton. He was mentioned in despatches in 1915 and gained the rank of Brevet-Major, R.A.M.C (T) He was one of the earliest to describe the new disease now commonly called "trench fever" but his most important work was carried out at Cambridge in collaboration with Dr J Barcroft and others on the later effects of gas poisoning and the results of oxygen treatment The conclusions may be summed up as follows: Gassed subjects develop a small degree of polycythæmia and there is delay in the length of time that it takes for the pulse to become normal after exercise After treatment for five days in an oxygen chamber the pulse returns to its normal value more quickly, the polycythæmia disappears, and the patient's symptoms—e g, the attacks of nocturnal dyspnœa, the præcordial pain—are much improved While working at Cambridge he also described a method of measuring dyspnœa by calculating the total pulmonary ventilation during the second, third, fourth, and fifth minute after a given exercise was completed and dividing this number by the pulmonary ventilation during four minutes of rest previous to the exercise This dyspnœa ratio was found to be the most constant of the respiratory data obtained. The value increased as the exercise became more strenuous, was lower with untrained than with trained individuals, and still lower in the case of certain pathological cases and of men who had been gassed.

At the end of the war Hunt returned to Guy's Hospital, taking up again the clinical and teaching work that he had left in 1915. In particular he threw much of his energies into the organisation of the massage department. He had been appointed physician in charge when the department was opened in 1913, and was also lecturer in medicine to the massage students. He used to visit all the medical cases for which exercises and massage were prescribed by members of the staff, although later on he gave up the nervous cases. He was particularly interested in the curative effect of physical exercise and massage on the heart and lungs, and as a result of his experience in the department he formulated definite rules by which exercises were graduated as regards their severity. It is fortunate that this work was published in the *Guy's Hospital Reports* of last year. For this purpose he divided heart cases into three groups: (1) cases which had recently suffered from acute carditis; (2) cases with signs of cardiac failure; (3) cases with effort syndrome. Exercises of gradually increasing difficulty were ordered, but the rate of increase was slowest in the first groups and most rapid in the last group. The masseuse was instructed to look for a rise in pulse-rate as the criterion as to whether the exercise was too hard or not. Closely related to this work is a paper, also in the *Reports*, dealing with the "pulse-ratio"—i.e., the ratio of the number of heart-beats, counted during the first two minutes after exercise, to the resting value for one minute. This method was introduced, as he found that the more usual clinical method of determining cardiac efficiency—viz., measuring the length of time it takes for the pulse to return to the resting value—led to uncertain results. The exercise chosen for the test is of the simplest kind—stepping on and off a block, 13 inches high, for three minutes. The number of steps per minute for a particular case is chosen, so that a pulse-ratio near to the value 2·5 is obtained. Knowing the number of steps that produces this value in the healthy trained individual (and calling it 100) it is possible to get an expression for the percentage efficiency of the individual in question. A further paper in the *Reports* on the exercises used in pulmonary cases must be read in the original, as a considerable variety of methods are used in cases of non-expansion of the lung after empyema, in pleurisy, and in the evacuation of bronchiectatic cavities. His work on physical exercises at Guy's Hospital led him to take a keen interest in the Chartered Society of Massage and Medical Gymnastics, of which he became a member of council in 1925, and for the last few years he lectured to its members. In 1923 he gave a special course of lectures on the treatment of heart disease to the Teachers' Association of the Chartered Society. In 1924 he contributed to the Modern Technique in Treatment series in THE LANCET an article on the Treatment of Functional Disorders of the Heart, which was widely appreciated.

At Guy's Hospital Hunt continued, as far as his health would permit him, the work he had begun at Cambridge. He was honorary secretary of the Clinical Uses of Oxygen Committee of the Medical Research Council. At the time of his death he had begun what would have developed into a very successful private practice, dealing specially with diseases of the chest, and, in particular, heart disease, and he published a number of clinical studies on this subject from time to time.

Dr. E. P. Poulton, to whom we owe much of this biographical sketch, adds: "No account of Hunt's life would be complete without an indication of his love of music which was associated with a considerable musical ability. He came from a musical family, and was a skilled viola player; his playing was much appreciated at Rugby, Oxford, and Guy's. He was greatly in demand at the hospital Christmas festivities in his younger days, while in later life he was a regular player in quartets. His music was the dominating interest of his life outside his work. He also sang tenor, and the present writer can testify to his power of singing difficult music at sight, both when he was a schoolboy in the choir at Rugby and later in the Oxford Bach choir. He well remembers Hunt's comical dismay at a senior Oxford don, enthusiastic but not always quite in tune, when the music was difficult. His music made him a combination of artist and physician. Golf and lawn tennis were his favourite games and at both of them he was a player of more than average ability.

"Perhaps his friends will chiefly remember him for his gentle and sympathetic personality. His musical temperament, his profession as a physician, and the fact that as a boy he was brought up among sisters, without a brother of his own, may all have been factors which helped to form a very lovable nature."

In 1915 Dr. Hunt married Miss Rosie Strauss, who survives him. His colleagues at Guy's and his many professional and private friends have sustained a great loss by his early death and will extend their deep sympathy to his widow, to his two little girls, and to his sisters in their bereavement.

---

## JOHN BASIL HALL, M.B., M.CH.CAMB., F.R.C.S. EDIN. & ENG., J.P.

BY the sudden death on Jan. 12th of Mr. Basil Hall at the age of 60 years, Bradford has lost something more than its principal surgeon, for Mr. Hall was a big influence in civic and professional life in the West Riding.

John Basil Hall was son of the late Dr. William Hall of Headingly, whose name is cherished in Leeds as a friend of necessitous school-children. Both his grandfathers were also in medical practice in Yorkshire. He was educated at King's School, Canterbury, and Pembroke College, Cambridge, going on to St. Thomas's Hospital, London, for his clinical studies, which he completed in 1892. After holding a series of resident appointments at the Leeds General Infirmary and some post-graduate study in Vienna, he settled in Bradford with the intention of limiting himself to surgical work; having obtained the F.R.C.S. Edin. in 1899 he soon became honorary surgeon to the Bradford Royal Infirmary, a position which he held for the statutory 20 years.

As a surgeon Mr. Hall's interests were wide. A densely populated manufacturing district afford surgical material of many kinds and his published clinical notes, all brief and to the point, are very various. His surgical colleagues at the infirmary speak of his work there as neat and dexterous, for he was by nature clever with his fingers; but they emphasise also the broad common-sense view which he took of his cases and the value to the institution of his orderly mind and retentive memory. He was himself watchful lest mere technique should cramp the development of surgical judgment, and he was apt to quote with approval the remark of Sir William Macewen that no one can become a good surgeon unless he is first a good physician. During the second and third years of the war Mr. Hall had a period of service in the Dardanelles with the Mediterranean forces, which he greatly valued in its personal and human aspect, although he returned with no illusion as to the value of military experience in dealing with sickness in civil life. As chairman of the building committee he was enthusiastic in his efforts to found a hospital in Bradford commensurate with the needs of the town and was instrumental in securing the new site on Daisy Hill on which, had it not been for the intervention of the war, the new infirmary would now be standing. At different times he presided over the Bradford and the Leeds Medico-Chirurgical Societies and he had been for long President of the Bradford Division of the British Medical Association, when, as a crown to his labours, he became President of the Association at its annual meeting in Bradford in 1924.

During his year of office the leisured mind and practical judgment which he brought with him ensured respectful hearing on deliberative occasions, and it fell to his lot to visit Canada to address the Ontario Medical Association and to represent the British Medical Association at the Atlantic City meeting of the American Medical Association. While still President, the Royal College of Surgeons of England conferred upon him the honorary Fellowship of the College.

Several years ago Mr Hall became a justice of the peace for the city of Bradford His favourite hobbies were fishing and motoring In 1898 he married Lisbeth, daughter of Mr Thomas Mackenzie, of Achnaaird, and he is survived by his widow and daughter

---

## WILLIAM JOHN NAISMITH, D.S.O., M.D , F.R.C.S EDIN.

Dr. W. J. Naismith, who has died at St Andrews at the age of 78, was the son of the late Dr. J. Naismith, deputy surgeon-general at Agra. He was born in India and at the age of 10 was sent to England to escape the Mutiny. Qualifying at Edinburgh in 1869 he settled in Ayr, where he became the first surgeon of the Ayr County Hospital, and where he held many public appointments. It was as an officer of the Ayrshire Yeomanry that he saw active service in the Boer War, for which he was mentioned in despatches and received the D.S O. Dr Naismith was a skilful and self-reliant surgeon. He was closely identified with public health work for his town and with training in ambulance work in early days. He was an enthusiast for athletics and was perhaps at his happiest when presiding over the smoking concerts organised after the Ayr annual sports and the Academy sports. At the time of his retirement in 1908 he received a warm tribute from the townsmen of Ayr, who had learned to appreciate his cheerful, debonair manners and his goodness of heart. Dr. Naismith was twice married and is survived by his widow and by one son and two daughters.

---

## EDWARD GRANVILLE BROWNE, M.B. CAMB., F.R.C P. LOND.

Prof. E. G. Browne, who died at Cambridge on Jan. 5th at the age of 63, was one of the most eminent of oriental scholars He was educated at Glenalmond, Eton, Cambridge, and St Bartholomew's Hospital, and although he never practised medicine, graduated as M.B at Cambridge in 1887 and later became F.R C P under a regulation which permits practitioners other than Members of the College to be elected on account of their distinction. In the year of qualification he received a Fellowship at Pembroke College, Cambridge, and soon afterwards became lecturer in Persian in the University, succeeding Charles Rieu as Sir Thomas Adams's professor of Arabic in 1902. Much travel and a phenomenal memory made him familiar with many Eastern peoples, and he was devoted to the study of oriental literature, history, and religion. Unlike many scholars, however, he was able to combine his scholarship with a real understanding of the living language and the living mentality of the races he studied. Nor was his original profession forgotten. His FitzPatrick lectures to the Royal College of Physicians were on Arabian Medicine, and he produced other work on the same subject. As a teacher he was regarded with the affection and respect which his high scholarship, his wisdom, and his disposition demanded.

---

THE LATE DR. GEORGE CHAPMAN —By the death of George Chapman, at his house at Hall Green, Birmingham, the medical profession in Great Britain loses its oldest member He was a student at Queen's College, Birmingham and qualified M R C.S. in 1860 and L.S.A. in 1868 Dr Chapman had reached the age of 103 years. He retired from practice at the age of 80, and remained in good health, taking walks in the open air until the day before his death.

# THE EXCRETION OF ALCOHOL IN URINE AS A GUIDE TO ALCOHOLIC INTOXICATION.

*At a meeting of the Medico-Legal Society held on Jan. 19th, with Sir William Willcox, Vice-President, in the chair,* Dr. Godfrey Carter read a paper with the above title He said that there was no subject in which medical evidence was more unsatisfactory than that appertaining to drunkenness, the evidences of which were very hard to reduce to a form that could be stated and still more to a formula that could be given to a bench of magistrates. Yet the recognition of the condition presented few difficulties at the time. Every member of a social group could say when a member of that group ceased to be normal; the general impression was made up of a number of small changes which could be sensed and analysed. But when, for legal purposes, it became necessary to apply a series of tests, such as poise, gait, ability to toe the line, smell of the breath, memory for recent and remote events, &c., it was universally agreed that the present tests were inadequate. No two men behaved exactly alike under the influence of alcohol. In consequence, many accused cases were wrongly dismissed, after serious motor accidents, for want of evidence sufficient to convict.

### *Present Tests.*

In the speaker's opinion too much was made of the smell of the breath. It did not increase pari passu with the amount of alcohol taken, but only indicated that some alcohol had been consumed. It had no positive value, but was important as negative evidence. There were five tests to which he attached importance—viz., flushed face, sweating, dilated pupils, congested eyes, and rapid pulse. These were present in nearly all cases. The problem set to the practitioner was, as Taylor put it, to determine whether "the person's mental condition which led to the proceedings and caused him to behave in the manner he did prior to arrest was due to alcohol." If so he was drunk. The police surgeon usually heard nothing of the many cases of drunkenness *settled* daily in the courts, but recently he had come into prominence through a number of more serious cases, those of drunkenness in charge of a motor-car. There had often been serious injuries and damage to property and the accused might be a person of social standing, who realised the gravity of the charge and met it with indignant denials. The time factor was of great moment; nothing sobered a man more quickly than finding himself in prison for a serious charge. His power of regaining control under such circumstances was striking and he would often pass the usual tests quite satisfactorily or fail in *one only*, ascribing any weakness to the shock of the collision and his anger at being wrongly accused.

### *The New Test.*

When the speaker heard of Dr. Southgate's test he began to see daylight. It appeared certain that there was a concentration of alcohol in the urine which indicated very strongly that the individual would be unfit to be in charge of a car. The defence of having taken a small quantity only could not be proffered; what was found in the urine must have gone in, by the mouth. He arranged for a record of appearance and behaviour to be kept in the police books for comparison with the tests and for the samples to be bottled quickly to avoid evaporation. An initial difficulty was found in obtaining samples, as the accused men could not be persuaded to micturate to order; this was overcome by leaving them in a cell with a urinal leading to a receiver in the next cell. The great value of the test would be in *borderland cases* where the symptoms were only moderate and the defence alleged that so little alcohol had been taken that the conduct could not be ascribed to its influence.

Dr. H. W. Southgate said that the test was the outcome of four years' research in human subjects on the alcohol concentration in blood and urine. He showed a number of slides illustrating five points: (1) the general shape of the blood-alcohol concentration curve compared with that of glucose; (2) the factors affecting the height of the alcohol curve; (3) that the concentration in the blood was proportional to the toxic effect produced; (4) that the concentration of alcohol in the urine was closely related to that in the blood and that one could be deduced from the other; and (5) examples of the tests used and demonstration of how their usefulness could be applied. The samples were taken from a vein and the alcohol estimated and calculated on a percentage basis in the usual way and expressed as milligrammes of alcohol in 100 g. of blood. The concentration curve of blood-alcohol rose very rapidly—in about an hour—to its maximum and slowly came down, taking about 12 hours to return to normal, which was probably zero. The rate of disappearance was practically a straight line, and this held for wide range of concentration and all the individuals tested, and could therefore be safely used as the basis of tests. The glucose curve rose with equal rapidity, but fell within about one and a half hours to the normal of about 80 mg. to 100 g. The kidney could keep back glucose until it reached quite a high blood percentage, but had not this power for alcohol, and even half a glass of beer caused alcohol excretion. The actual maximum concentration varied with the dose. When alcohol was taken with food the concentration rose more slowly and never reached such a high maximum as when the dose was taken on an empty stomach. Some of the alcohol was held between the interstices of the food, but not enough to account for the difference, and what became of it was not known. The descending curves of concentration with and without food were parallel when the subject took exercise as well as when he rested. The tolerance of individuals varied very much according to their habits. The speaker showed a test taken by Dr. Schweisheimer in 1913, which compared the concentration figures of four subjects, one of whom was an abstainer, one a moderate drinker, and two heavy drinkers. The abstainer showed a high concentration; the chronic drinkers relatively low ones, as the alcohol never "got going" in their blood. Nevertheless, the factor of personal idiosyncrasy was very great, and it was impossible to be certain from the percentage in the urine how much alcohol had been taken.

Gréhant was the first to show that the concentration of alcohol in the blood was the measure of its toxic effect. When the body's maximum was reached the curve turned over and ran flat for a while (Gréhant's plateau). The subject was then dead drunk, and the alcohol escaped by any pore it could find. There was no difference in practice between the toxicity of a rising and a falling concentration measured on the same level. Comparison of the relative effects of whisky and stout, containing an identical amount of alcohol, showed that the concentration with whisky reached a higher maximum much more quickly than with stout, had a greater effect on the subject, and passed off more quickly. This was because the stout took much longer to drink. Toxicity was measured by the subject's ability to draw a square with its diagonals inside a circle. Miles showed that the concentration in the urine passed that of the blood almost at once and maintained a fairly constant relationship with it (1·35–1·45) whatever food is taken and whatever urine is passed. This point was important, as the evidential value of the test depended on it. One slide showed the concentration in the urine of four motorists arrested for drunkenness. One case, who had 257 mg. 15 minutes after arrest, was 40 minutes later pronounced fit by the police surgeon and released. A sample of urine taken some time after arrest would naturally not give the concentration at the time of arrest. He proposed, therefore, that this should be calculated in a standardised test by taking another sample at a measured time afterwards and plotting the concentration at arrest on the resulting curve, the time between arrest and the taking of the first sample being known. He pleaded that any standard submitted should be based on behaviour tests made with individuals of varying tolerance, each of whom had a dose that would make his concentration the same as that of the others. This test would show what the average concentration was, beyond which a person was not fit to be in charge of a car. Dr. Southgate then described the methods by which the alcohol content was estimated.

*Discussion.*

Dr. Mackenzie Wallis said that he could confirm Dr. Southgate's findings from his own work on blood-alcohol concentration in hospital cases, mostly intoxication. Cases of alcoholic poisoning, especially those being treated by gradual reduction of alcohol, often showed albuminuria, and this he thought of importance. Every case differed in regard to his tolerance for alcohol. Another factor that must be considered was the time of day and the question of fatigue; there was much less tolerance to alcohol in the morning than later in the day. Experiments should be made as to the effects of the same dose of alcohol after a heavy meal of varying dietaries.

Dr. Roche Lynch asked whether evidence obtained by such a stratagem as Dr. Carter described would admissible in a court of law; whether Dr. Southga had investigated the relation of the alcohol concent tion to other diseases such as nephritis and to abn malities in the basal metabolic rate; and whether was possible to judge from an analysis done some hou later the height to which the alcohol curve had ris at its maximum. He understood that the absorptio of alcohol after a meal containing a lot of fat wa much slower than after proteins and carbohydrate Apparently the maximum concentration was much th same in chronic drunkards and in total abstainers, ye with the same dose the former might show no evidenc of drunkenness while the latter showed marked signs

Dr. Morgan Finucane pointed out that the pamphle issued by the Board of Control ("Alcohol: Its Actio on the Human Organism") stated that very little o no alcohol was excreted in the urine. There was n public demand for boiling down drunkenness to a test, and it could not be done. It was far better to rely on the experience and common sense of the police and the observers of the conduct of the accused. He did not agree that the odour of the breath was insignificant or that sweating was a valuable sign, and regarded Dr. Carter's other four signs as trivial.

Mr. Ernest Williams said that the test would certainly be admissible as evidence.

Dr. A. S. Woodwark asked how it was possible for a man to be sober an hour after arrest, as Dr. Carter said, when the alcohol concentration curve fell steadily. He felt that no definite pronouncement could be made until many more experiments had been performed on the alcohol concentration in relation to various types of food. The same amount of sugar in the blood might produce very different effects in two different cases; alcohol might vary in the same way, and the blood-alcohol not give sufficient evidence as to the capacity of the individual for managing a vehicle.

Sir Bernard Spilsbury said that a fallacy might arise through the varying amount of urine contained in the bladder before the alcohol was taken. It would almost certainly be impossible to get a second specimen from a drunken man. There was an immense amount still to be done, especially on the effect of such things as kidney disease on excretion of alcohol, before a test could be submitted for legal use.

Dr. B. A. Levinson pointed out that the refusal to submit to a test such as this would be strong evidence against the accused. In his opinion magistrates longed for some standard; he had seen most conflicting evidence brought forward by opposing doctors. The new test would be of extraordinary value in such cases, especially to rebut a defence claiming that no alcohol had been taken.

Dr. Carter, in reply, said that the matter was only in an experimental stage, but Dr. Southgate had definitely proved that alcohol was excreted in the urine.

Dr. Southgate, in reply, said he had only had one case of renal insufficiency and this showed a lowered value. The report of the Liquor Control Board referred to the total output which was quite different from the concentration. In his opinion no man with more than 150 mg. of alcohol per 100 c.cm. of urine was fit to be in charge of a car.

## Medical News.

UNIVERSITY OF LONDON.—At the First Examination for medical degrees held in December last, 111 candidates satisfied the examiners, and the following were awarded a mark of distinction:—

*Inorganic Chemistry.*—Alan Ruscoe Clarke, Haileybury College, Marian Josephine Cunning, London (R.F.H.) School of Medicine for Women, and Philip Frankenberg, St. Bartholomew's Hospital.
*Physics.*—Eric Stuart Harverson, University College, and Moses Shorvon, King's College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council of the College on Jan. 14th, Sir John Bland-Sutton, President, being in the chair, it was resolved that for the rest of January and during February the museum be kept open till 5 P.M. instead of being closed at 4 P.M.—A further application from Mr. F. W. Axham for restoration to the Membership of the College was considered, but the Council did not see fit to rescind the resolution of July 13th, 1911, removing Mr. Axham from being a Member of the College.—It was agreed that a gown for Licentiates in Dental Surgery of the College be instituted and that the following addition be made to Section XXVI. of the Regulations of the Council relating to Academical Costume:—

> The gown for Licentiates in Dental Surgery shall be a black stuff gown similar in shape to the Fellows' and Members' gowns, with facings of crimson cord and with a sleeve looped with crimson cord.

—The President reported that Sir Berkeley Moynihan had consented to deliver the next Hunterian oration and accordingly declared him to be appointed Hunterian orator for 1927. The President also reported that he had appointed Sir John Lynn-Thomas as Bradshaw lecturer, and Prof. G. Elliot Smith as Thomas Vicary lecturer for the ensuing year.—A letter was read from Mr. Raymond Johnson resigning his membership of the Court of Examiners. The President stated that the vacancy on the Court of Examiners thus occasioned would be filled up at the ordinary Council on March 11th.

The diploma of F.R.C.S. was conferred upon Laurence Frederick O'Shaughnessy, who had previously passed the necessary examinations and had now complied with the by-laws. The diploma of M.R.C.S. was conferred upon S. A. Antoun, Birmingham; Hilda M. King, Royal Free and St. Mary's; and Nellie L. Pyman, Charing Cross Hospital.

Diplomas in Public Health were conferred (jointly with the Royal College of Physicians of London) on the following 16 candidates:—

P. L. T. Bennett, Margaret E. Bjorkegren, and M. A. B. Brito-Mutunayagam, Univ. Coll.; A. B. Davies, Guy's and King's Coll.; Sylvia V. Elman, Royal Inst. Public Health; W. D. Forgrave, Belfast and King's Coll.; Janet M. Gillison, Edinburgh and King's Coll.; A. W. Grace, Univ. Coll.; F. V. Jacques, Bristol and Univ. Coll.; C. R. Lane, Oxford and King's Coll.; J. H. Porter, Cambridge and Royal Inst. Public Health; W. O. Pou, Univ. Coll.; A. S. Sachdev, Punjab and Royal Inst. Public Health; J. Singh, Punjab and Univ. Coll.; B. K. Vaidya, Bombay and Univ. Coll., and H. C. M. Williams, St. Bart.'s.

Diplomas in Laryngology and Otology were conferred upon:—

P. V. Cherian, J. M. Damany, W. J. McNally, and N. C. Ramchandani.

Diplomas in Tropical Medicine and Hygiene were conferred upon:—

Winifred D. Cargill, O. F. Conoley, R. A. Mansell, and C. H. H. Robertson.

Diplomas in Psychological Medicine were conferred upon:—

N. A. Albiston, H. E. August, A. A. Bell, Eleanor M. Creak, J. H. Cuthbert, H. S. Forbes, T. R. Forsythe, R. F. Hewlitt, R. M. Macfarlane, J. McGarvey, E. D. T. Roberts, and F. C. M. Taylor.

Dr. T. A. McCullagh, of Bishop Auckland, has been appointed deputy lieutenant for the county of Durham.

STUDY OF VENEREAL DISEASES.—A meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos-street, Cavendish-square, London, W., on Friday, Jan. 29th, at 8.30 P.M. Papers will be read by Dr. Dorothy Logan and Dr. Violet Russell on the Diagnosis and Treatment of Urethritis and Cervicitis in the Female, and a discussion will follow.

HUNTERIAN SOCIETY.—At a meeting to be held on Monday, Jan. 25th, at 9 P.M., in the Hastings Hall, British Medical Association, Tavistock-square, London, W.C., Sir James Berry will deliver the Hunterian Lecture, on Some Clinical Aspects of Simple Goitre with remarks on its Causation. After the lecture, which will be illustrated by the epidiascope, there will be a discussion in which Dr. Strickland Goodall, Mr. T. P. Dunhill, and Dr. Scott Williamson will take part.

NEW UNION HOSPITAL FOR BARTON.—The Barton-upon-Irwell guardians are to build at once at Davyhulme, near Manchester, a hospital which will be one of the best equipped in the country, and is to be completed in about 18 months. The new buildings will be erected on a site of 33 acres and will cost about £300,000. There will be a maximum of 500 beds available. The medical and clinical appliances include a laboratory for pathological work and an electrical and X ray department, and amongst the amenities will be a single-storey block for healthy children.

GERMAN CONGRESS ON PSYCHOTHERAPY.—In connexion with the Wiesbaden Congress of Internal Medicine, the first general medical congress of psychotherapy will take place at Baden Baden from April 17th to 19th next. The subject will be dealt with in a comprehensive manner under twelve headings by psychotherapists from Berlin, Vienna, Budapest, Munich, Heidelberg, Bonn, Giessen, Frankfort, Münster, Tübingen, Basle, and Zürich. Scientific contributions for this congress should be addressed to Dr. med. et phil. Eliasberg, Grosshesselohe, Munich, and applications for tickets to Dr. med. Benno Hahn, Maria-Victoria Strasse, 6, Baden-Baden.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 41 cases were considered and £451 18s. voted to 32 applicants. The following were some of the cases relieved:—

M.R.C.S. 1915, M.B. 1922, aged 35, married, three children, aged 9, 6, and 1 year. With army gratuity and savings bought a practice which turned out badly and could not keep up instalments, so he went to moneylenders and eventually became bankrupt. Afterwards, with some £60 which he had left, and a contribution of £50 from friends, started a practice in the Midlands with good prospects. The Professional Classes Aid Council investigated the case and suggested coöperation, with which the Committee agreed and voted £24 to be disbursed by them.

Widow, aged 60, of M.D. Edin. who practised in Wales and died in 1906. Two children: daughter, aged 20, a dispenser earning £3 a week but not living at home, and son, aged 23, with defective hearing, who is unable to get employment. Lives with applicant. Only income £20 per annum, and £10 10s received from letting rooms. Has applied for the Epsom Pension. No rent, but rates amount to £9 per annum. Voted £12 in 12 monthly instalments.

Widow, aged 59, of M.R.C.S. 1891 who practised in England and then went to New Zealand and died in 1905. Applicant and her daughter lived on the £3000 left by the doctor, but £1700 of this was lost by bad investment. Daughter not strong but is nursing in a sanatorium, receiving £2 10s. a month. Applicant has had to give up nursing at present owing to bad health. The Committee voted £10.

M.R.C.S. Eng. (St. George's), aged 71, unmarried. Unable to obtain locums owing to age. Suffers from rheumatism. £100 War Loan held by bank against overdraft. Has been in receipt of the Old Age Pension for the past twelve months. Board and lodging 25s. a week. Voted £50 in 12 monthly instalments.

M.R.C.S. Eng. 1897 (Middlesex), aged 54, who up to 1923 had a practice in the Midlands and has since taken locums. Unable to get work and since Christmas 1923 has lived on savings, and been helped through the charity of friends. Had to apply recently to the guardians. Rent of room 12s. 6d. a week. Voted £9.

Widow, aged 68, of M.R.C.S. Eng. (University College) who practised in the provinces and died in 1890. Applicant has maintained herself ever since, and it is only owing to an accident last August that she has now applied for assistance. She was in bed for 9 weeks. Only income, Epsom Pension £40, and 8s. a week from her married daughter; her rent amounts to 10s. a week. Voted £18 in 12 monthly instalments.

Daughter, aged 53, of L.R.C.P. 1864 (St. Bart.'s) who practised in the Midlands and died in 1881. Applicant is unable to earn her own living as she has to look after her mother aged 85 who is an annuitant of the Fund. Mother has the Old Age Pension and help from our Guild and our annuity of £30 per annum. The rent is paid by applicant's sister. Voted £18 in 12 monthly instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

A Hospital Economy.—During the past year the Royal Free Hospital, London, has saved over £500 by washing and resterilising used gauze and bandages.

Norfolk and Norwich Hospital.—The board of management report the "stupendous" annual total of 1275 accident cases, of which 20 a week are motoring casualties. A new children's ward has just been opened.

At the quarterly meeting of the Directors of the Naval Medical Compassionate Fund, held on Jan 19th, at which Surgeon Vice-Admiral Sir Joseph Chambers, Medical Director-General of the Navy, occupied the chair, a sum of £105 was distributed among applicants.

Richmond Hospital Association.—Last week an association was started at Richmond (Surrey) for the benefit of its Royal Hospital, with the approval of the President of the appeal, the Duke of York. Richmond Royal Hospital needs £11,000 a year for its maintenance, but out of a population of 280,000 in the districts it serves only 600 people contribute. The association aims at obtaining members at £1, associates at 10*s.*, and junior members at 5*s.* a year.

Improvements at Cheltenham General Hospital.—It is proposed to expend £14,000 upon enlargement and improvement. In 1922 £6000 contributed by the British Red Cross Society was devoted to the improvement of the out-patients' department and the provision of a new orthopædic ward. It is now reported that much of the existing X ray installation is obsolete, and that the electrotherapeutic apparatus falls below the present standard. The surgical side for out-patients is very unsatisfactory, and there is no dental room.

Carter Bequest Hospital, Middlesbrough.—Last week Sir Hugh Bell opened a new hospital provided from a bequest of £40,000 left some 20 years ago by the late Alderman Thomas Carter, a former Mayor of Middlesbrough. Its erection was postponed by the war, and in the meantime the fund accumulated to £100,000. The building, which stands in four acres of land, contains 52 beds, and there will be no resident medical officer. Any medical man may recommend a patient and continue in attendance upon him.

Yorkshire Cancer Campaign.—Viscount Lascelles presided at a meeting held at Leeds on Jan. 18th to inaugurate the Yorkshire Cancer Campaign to establish and equip a cancer research centre for Yorkshire. It was announced at the end of the meeting that the first subscription list had reached £50,000; the sum of £75,000 is required as a minimum. Sir Algernon Firth promised to give £20,000 in addition to the £5000 he has already offered to the University of Leeds towards the erection of a pathological institute in which special facilities will be offered to cancer research students.

Courses at Maudsley Hospital.—Two series of clinical demonstrations are at present in progress at the Maudsley Hospital, Denmark Hill, London, S.E. On Wednesdays, at 2.30 P.M., Dr. Edward Mapother demonstrates Functional Mental Syndromes, whilst on Mondays at the same hour Dr. Mary Barkas deals with Mental Disorders associated with Organic Disease and Mental Symptoms and their Genesis. A discussion of cases in the hospital is held in the wards every Tuesday at 11.30 A.M., and there is a monthly meeting on the last Friday of each month at 4.30 P.M. at which a group of patients from one of the L.C.C. mental hospitals is shown. All these clinical facilities are open to medical practitioners and students without fee.

A British Trust for Spahlinger Treatment.—It is announced that a Spahlinger fund is to be created by public subscription to finance a British campaign on behalf of the Spahlinger treatment of tuberculosis, and to enable a board of British trustees to take over the Spahlinger estates and laboratory at Geneva, and to produce the necessary sera so that they may become available for use in Britain. The new appeal is to be sent out from Messrs. Brunner Mond's, and is to be made in the first place to employers of labour. In the first instance £40,000 will be asked for, but later a general appeal to the public will be made to raise the fund to £100,000 in order to secure a greatly increased output of the Spahlinger products and to establish an institute in England which would make them generally available to the medical profession. The first trustees of the fund will be Sir Arthur Steel-Maitland (the Minister of Labour), Mr. Tom Shaw, Sir Alfred Mond, and Sir Bruce Bruce-Porter. By private appeals several thousand pounds have already been raised. The first object of the fund is, it is stated, to set Mr. Spahlinger and his colleagues free to carry on their work without financial worries.

Charing Cross Hospital Institute of Pathology. It has been decided to offer to the general practitioner the scientific facilities provided by the Charing Cross Hospital Institute of Pathology at a scale of fees which will bring pathological, bacteriological, and chemical examinations within reach of his poorer patients, and greatly extend his opportunities for the investigation of his more obscure cases. Results will be posted within 24 hours when possible, or in the shortest time the nature of the investigation will permit. Arrangements may be made for patients to be visited in their own homes or to attend the laboratories, the former necessarily involving an increase in the cost. Tubes, pipettes, and other apparatus may be obtained upon request, accompanied by such special instructions as the director of the institute may consider desirable. All reports will be signed by Dr. A. Piney, the director of the Institute of Pathology. The following examples of the scale of fees are taken from the schedule: Quantitative estimation of sugar in blood, 5*s.*; Wassermann reaction, 5*s.*; differential blood count, 10*s.*; histological section, stained and mounted with report, 6*s.* 6*d.*; examination of fractional test-meal, 10*s.* 6*d.*; verification of the presence of tubercle bacilli in cerebro-spinal fluid, urine or sputum, by animal inoculation, 17*s.* 6*d.* All communications and specimens should be addressed to the Secretary, Charing Cross Hospital Institute of Pathology, 62, Chandos-street, Strand, London, W.C. 2.

# Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

## SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.
Thursday, Jan. 28th.—4.30 P.M.—*The following papers will be read:*—A. C. Seward: The Cretaceous Plant-Bearing Rocks of Western Greenland. W. L. Balls and H. A. Hancock: Measurements of the Reversing Spiral in Cotton Hairs. R. H. Burne: A Contribution to the Anatomy of the Ductless Glands and Lymphatic System of the Angler Fish (*Lophius Piscatorius*.) (Communicated by Sir Arthur Keith.) I. Gordon: The Development of the Calcareous Test of *Echinus miliaris*. (Communicated by Prof. E. W. MacBride.) *Papers to be read in title only:* F. G. Gregory and L. Batten: A Critical Statistical Study of Experimental Data on the Effect of Minute Electric Currents on the Growth Rate of the Coleoptile of Barley. (Communicated by Prof. V. H. Blackman.) H. M. Fox: Chlorocruorin: a Pigment Allied to Hæmoglobin. (Communicated by Prof. J. Stanley Gardiner.)

**ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.**

**Monday, Jan. 25th.**

GENERAL MEETING OF FELLOWS: at 4.30 P.M.
*Discussion* on
Hyperpiesis.
*Opener:*
The Right Hon. Lord Dawson of Penn, to be followed by Prof. F. R. Fraser and others.
ODONTOLOGY: at 8 P.M.
*Casual Communication:*
Mr. Walter Harrison and Mr. E. W. Lowe: Notes of a Complicated Removal of a Third Lower Molar—Fatal Sequel.
*Paper:*
Mr. A. W. Wellings: Some Points in the Anatomy of the Capillaries of the Tooth Pulp.

**Tuesday, Jan. 26th.**

MEDICINE
COMPARATIVE MEDICINE } at 8.30 P.M.
*Discussion:*
Hodgkin's Disease in Man and Animals.
*Openers:*
Sir Humphry Rolleston (Medicine)
Prof. Wooldridge (Comparative Medicine).
*Other Speakers:*
Dr. Morley Fletcher, Mr. W. Horner Andrews, Mr. L. Pugh.

**Wednesday, Jan. 27th.**

COMPARATIVE MEDICINE: at 5 P.M.
*Papers:*
Prof. R. H. A. Plimmer: The Relation of Quantity of Vitamin B to Quantity of Food.
Prof. J. C. Drummond: New Facts concerning the Fat-Soluble Vitamins.

**Thursday, Jan. 28th.**

UROLOGY: at 8.30 P.M.
*Discussion* on
Pyelography.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W
Monday, Jan. 25th.—8.30 P.M., Discussion on Manipulative Treatment in Medicine and Surgery, to be introduced by Mr. R. C. Elmslie and Mr. W. R. Bristow.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, Jan. 25th.—5 P.M., Sir Arthur Keith: The Taungs Anthropoid: its Zoological and Geological Position.

WEDNESDAY.—5 P.M., Fossil Anthropoids of Europe and of Asia.

FRIDAY.—5 P.M., The Kivu Gorilla and its Bearing on the Problems of Human Evolution.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Jan. 25th, to SATURDAY, Jan. 30th.—Lecture Hall of the Medical Society of London, 11, Chandos-street, W. Thurs., 5 P.M., Dr. H. C. Cameron will lecture on Catarrhs and the Catarrhal Child. This lecture is free to members of the medical profession.—BETHLEM ROYAL HOSPITAL, Lambeth, S.E. Lecture-demonstrations at 11 A.M. Tues., Dr Porter Phillips: The Psychoses. Sat., Dr. Porter Phillips: Medico-Legal Aspect of Insanity.—NORTH-EASTERN FEVER HOSPITAL, St. Ann's-road, Tottenham Wed., 2.30 P.M., Sat. 11 A.M., Dr. Frederic Thomson Demonstration in the Diagnosis and Treatment of the Acute Infectious Diseases.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. Special course, daily lectures, and demonstrations in all departments.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street. Special course in the Diagnosis and Treatment of Common Diseases of the Nervous System. Lecture-demonstrations at 5 P.M. throughout the week.—WESTMINSTER HOSPITAL. Wed., 2 P.M., Mr. E. Rock Carling: Special clinical surgical demonstration. All information as to fees, &c., from the Secretary of the Fellowship.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Jan. 25th.—10 A.M., Surgical Out-patients: Mr. W. E. Tanner. *10.30 A.M., Gynæcological Operations:* Mr. A. E. Giles; Throat, Nose and Ear Operations: Mr. W. Ibbotson. 2 P.M., Medical, Surgical, and Gynæcological Clinics, Operations. 6.30 P.M., Venereal Department.

TUESDAY.—2 P.M., Medical, Surgical, Throat, Nose and Ear Clinics, Operations. 4.30 P.M., Mr. E. Miles Atkinson: Acute Infections of the External Auditory Meatus.

WEDNESDAY.—10.30 A.M., Surgical Operations: Mr. E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 5.30 P.M., Venereal Department.

THURSDAY.—10.30 A.M., Dental Out-patients: Mr. E. S. Pierrepont. 2 P.M., Medical, Surgical, and Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

FRIDAY.—10.30 A.M., Eye Operations: Mr. N. Fleming. 2 P.M., Surgical, Medical, and Children Clinics, Operations. 3 P.M., Gynæcological Clinic. 6.30 P.M., Venereal Department.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

TUESDAY, Jan. 26th.—5 P.M., Dr. H. W. Barber: The Erythrodermias.

THURSDAY.—5 P.M., Dr J. M. H. MacLeod: Pemphigus.

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY.

WEDNESDAY, Jan. 27th.—3.30 P.M., E. W. Fish: The Mouth as a Focus of Infection.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Jan. 29th.—3 P.M., Mr. Gill-Carey: Diagnosis of Sinus Disease.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.

WEDNESDAY, Jan. 27th.—Dr. Harrison: Reducing Substances in the Urine.

THURSDAY.—4 P.M., Mr. T. Higgins: Hip Cases: A Diagnostic Review.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

THURSDAY, Jan. 28th.—5 P.M., Mr. T. B. Davies: Ante-Partum Hæmorrhage.

ST. MARY'S HOSPITALS, MANCHESTER, POST-GRADUATE LECTURE.

FRIDAY, Jan. 29th.—4.30 P.M. (at Whitworth-street West Branch), Mr. J. Morley. Acute Appendicitis in Infants

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.

FRIDAY, Jan. 29th.—3.30 P.M. (at the Royal Infirmary), Dr. Mouat: The Technique of Local Anæsthesia in Minor Operations.

# Appointments.

DAVIES, L. MEREDITH, M.D., B.Ch. Oxf., D.P.H., has been appointed Medical Officer of Health for Northamptonshire.

FALCONER, KINLOCH, M.D., Ch.B. Glasg., D.P.H., Medical Officer of Health, Durham Rural District.

HODGSON, J. F., M.D., Ch.B. Manch., D.P.H., re-elected Honorary Surgeon to the Royal Halifax Infirmary.

MILNE, V. E., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health, Walsall Rural District Council.

POWER, R. W., M.B., B.Ch. Dub., D.P.H., Hon. Orthopædic Surgeon to the Hereford General Hospital.

Willesden General Hospital, Harlesden: WILLIAMS, T. PEARSE, M.D., B.S. Lond., M.R.C.P. Lond., Physician with charge of Out-patients; PHILLIPS, L., M.S., M.B. Lond., F.R.C.S. Eng., Gynæcologist with charge of Out-patients.

# Vacancies.

*For further information refer to the advertisement columns.*

*Barnsley County Borough.*—Asst. M.O.H., &c. £600.
*Bradford Children's Hospital.*—H.S. £100.
*Brighton, Lady Chichester Hospital for Early Nervous Breakdown.*—H.P. £100.
*Bristol Eye Hospital.*—H.S. £150.
*Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.*—Res. H.S. At rate of £75.
*Dundee Royal Infirmary.*—Hon. Asst. Ophth. S.
*Edinburgh, Royal Infirmary.*—Two Asst. M.O.'s. £460 and £350 respectively
*Exeter, Royal Devon and Exeter Hospital.*—Sen. H.S. £200.
*Guy's Hospital.*—Phys. for Psychological Med.
*Hertford County Hospital.*—H.S. At rate of £150.
*Hospital for Sick Children, Great Ormond street, W.C.*—Res. Med. Supt. £300.
*Hull Royal Infirmary.*—Asst. H.P. At rate of £130.
*Leeds Public Dispensary.*—Sen. Res. M.O. £200.
*London Lock Hospital, 91, Dean-street, W.*—H.S. At rate of £200.
*Manchester, Ancoats Hospital.*—H.S. At rate of £100. Also Anæsthetist. 10s. 6d. each attendance.
*Manchester Committee on Cancer.*—Special Investigation Officer. £600.
*Northamptonshire County Council.*—Tuberculosis Officer. £750.
*North Middlesex Hospital, Edmonton, N.*—Anæsthetist. 2½ gs. per session.
*Nottingham General Dispensary, Broad-street.*—Res. Surg. £250.

*Rochester, St. Bartholomew's Hospital.*—H.P. At rate of £200.
*Royal Northern Hospital, Holloway, N.*—Asst. Surg. O. £150.
*Southampton, County Borough Isolation Hospital.*—Res. M.O. £300.
*Sudan Medical Service.*—Four M.O.'s. £E.720.
*Ventnor, Isle of Wight, Royal National Hospital for Consumption and Dis. of Chest.*—Jun. Res. M.O. At rate of £250.
*Warrington, Lancashire County Mental Hospital, Winwick.*—Deputy Med. Supt.
*West London Hospital, Hammersmith, W.*—Asst. Path. £250.
*Wilts County Council, Venereal Diseases Clinic, Swindon.*—Part-time M.O.'s. £1 11s. 6d. per session.
*Wolverhampton and Staffordshire Hospital.*—H.S. At rate of £150.
*Worcester General Infirmary.*—Jun. Res. M.O. £120.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at Newport, Yorks, E. Riding; Insch, Aberdeenshire; and at Cumbernauld, Dumbartonshire.

A vacancy for a Medical Referee under the Workmen's Compensation Acts (Northern Ireland), 1906 to 1923, is announced. Application should be made to the Secretary, Ministry of Labour, 7, Upper Queen-street, Belfast, not later than Feb. 6th.

# Births, Marriages, and Deaths.

## BIRTHS.

CROOK.—On Jan. 18th, 1926, at 15, South Eaton-place, London, S.W., to Elizabeth, wife of Eric A. Crook, F.R.C.S.—a son.

PORTEOUS.—On Jan. 13th, at Glencoe, Lower Common South, S.W., the wife of A. B. Porteous, of a son.

POTTINGER.—On Dec. 13th, 1925, at Poona, India, the wife of Captain D. Pottinger, R.A.M.C., of a son.

SHEARWOOD.—On Jan. 17th, at Normanton-road, Derby, the wife of Dr. A. L. Shearwood, of a daughter.

## MARRIAGES.

HOLLOWAY—DIXON.—On Jan. 9th, at St. Andrew's Parish Church, Shoebury, Norman Maberly Holloway, L.D.S. R.C.S., to Barbara Mary, only daughter of Mr. and Mrs. Timothy Dixon, of Thorpe Bay, Essex.

## DEATHS.

BLOXAM.—On Jan. 12th, John Astley Bloxam, F.R.C.S., J.P., of The Old Malt House, Bourne End, Bucks, aged 82 years.

HALL.—On Jan. 12th, suddenly, at Park View, North Park-road, Bradford, John Basil Hall, J.P., M.Ch., F.R.C.S.

HODGSON.—On Jan. 12th, at the Samaritan Hospital for Women, Dorothy Margaret Hodgson, M.R.C.S., L.R.C.P., the wife of Dr. R. G. K. Hodgson, of Andover, Hants, aged 29.

MACLEAN.—On Jan. 15th, at Balham High road, S.W., James Newlands Maclean, M.B., C.M. Glasg., aged 63.

WILSON.—On Jan. 13th, at a nursing home in Liverpool, Frederick Perera Wilson, M.D., of Rodney-street, Liverpool, and Windbourne, Freshfield, Liverpool, aged 40 years.

WOOD.—On Jan. 14th, at Waverley-road, Enfield, Edward Wood, L.S.A., M.R.C.S., L.R.C.P.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## SMALL-POX AND VARIOLATION IN A VILLAGE IN PALESTINE

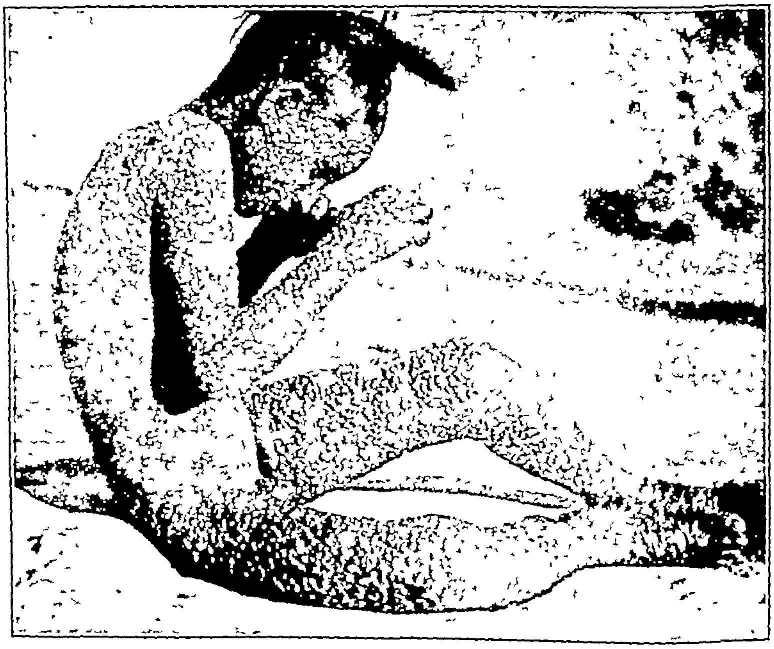
IN DECEMBER, 1921.

[ABRIDGED.]

BY JOHN MACQUEEN, M.B., C.M. EDIN.,
DEPARTMENT OF HEALTH, JERUSALEM.

VARIOLATION is the inoculation of individuals with variolous matter from the vesicles of a person suffering from small-pox, with a view to protecting them from the disease. In India there was a special worship defined in the Atharvaveda, and special prayers were to be said by the Brahmins when performing the operation of inoculating the virus. It was almost certainly known when the Charaka Samhita and the Susruta Samhita were written. In Africa Ruffer and Fergusson found an eruption on the skin of a mummy belonging to the period 1200 to 1100 B.C., which was suggestive of small-pox. It was apparently introduced into America by the Spaniards and by slaves brought from Africa.

FIG. 1.



Showing distribution of rash in a bad case.

For the study of the spread of small-pox recently in countries surrounding or connected by trade routes with Palestine, the returns from Paris, Constantinople, Egypt, and the League of Nations were available. What is of most interest is the connexion of the disease with the Moslem pilgrimage to Mecca in 1921. The Palestine pilgrims were detained at the quarantine station at Tor on the Red Sea, and arrived back in the country about Sept. 9th. The medical officer who had accompanied them reported that there had been ambulant cases in Mecca. In Dawaimeh village there had been no cases since the war, but the villagers stated that there had been three epidemics during the last 50 years. Certainly numbers of them were pock-marked.

The Turks performed vaccination spasmodically. They employed vaccinators for this purpose, and Palestinian doctors think that about 10 per cent. of the population of the country were vaccinated in this way. In Dawaimeh a much larger proportion than this had been variolated in their youth. Indeed, the majority still show the scar of this operation on the web between the forefinger and thumb.

### *History of Inoculation.*

It is worth while recalling the story of the introduction of variolation into Western countries. Lady Mary Wortley Montagu saw and learned the method in Constantinople in 1717, and had the operation performed on her son. She described it in a letter to a friend in England, where it soon became popular and eventually spread from there to Europe and America. The procedure in Turkey was to remove the contents of a vesicle (not a pustule), preferably the vesicle of an inoculated case, and introduce it by means of an abrasion, incision, or puncture. Rosenau describes the Chinese method as follows: "They inoculate usually by plugging the nostrils with cotton previously saturated with a mixture of water and pustular crustaceous matter taken from the eruption of a small-pox patient; less commonly by blowing the crushed fresh crusts into the nostrils through a bamboo pipe." Inoculation as performed in Britain is described by the late Dr. C. B. Ker: "Clear lymph from the vesicle preferably of an inoculated case was inserted by means of a lancet into the skin of the upper arm. Four days later papules appeared at the site of inoculation and formed pustules on the seventh day. There was fever and subsidiary pustules round the site of inoculation, and on the eleventh day the temperature fell and a generalised eruption appeared on the other parts of the body and ran a normal if somewhat rapid course." The discussion on the relationship of cow-pox to variola is age old, the established view being that cow-pox is small-pox modified by transmission through the cow. Goat-pox is comparatively common in Palestine.

### *The Epidemic in Dawaimeh.*

Dawaimeh lies among the western foothills of the Judean range, a four hours' ride in a direction west by south from Hebron. Its people are strong and healthy and well-suited for the pursuit on which a large number of them depend for a livelihood, for they are thieves of considerable distinction. It is told of them that during the war a troop of Turkish cavalry visited their village when touring the country to commandeer horses for the army. Their commander told the mukhtar of Dawaimeh that the village must provide ten by the following morning, otherwise the place would be burnt down. Next morning they were duly handed over to the Turks. It was not until they had the whole heat of a day's march between themselves and the mukhtar and arch-chief of Dawaimeh that they realised that their total number of horses had not been increased by a single animal. Hussein had caused his minions to steal ten horses from them during the night, and had presented them with a similar number in the morning! This story somewhat consoled me, because I had visited Dawaimeh on Dec. 19th, stayed the night with Hussein, seen the original case of small-pox, satisfied myself with regard to the measures being taken and that there were no further cases there, when all the time there were hidden in the village and surrounding caves over 300 children who had been variolated. Most of these must have had wounds at the site of inoculation at that time, a considerable number had already developed an eruption, many were very ill, and a few had almost certainly died. The original case, a negress servant of Hussein's, was first seen by a doctor on Dec. 13th, 1921, and was already in the pustular stage. She was isolated in a tent some distance from the village, disinfection was carried out, and vaccination begun. No more cases were discovered, and for some days all appeared to be going well. But the mukhtar had enemies who made it known that a few days before the case of the negress had been reported the village "doctor" Shaheen had, with the sanction and encouragement of the mukhtar, successfully inoculated from the original case no less than 300 children. Too successfully indeed had he done his work. One-half of the 300 children were said to have developed an eruption, many were seriously ill, some had died, and cases of true small-pox contracted from those inoculated were beginning to make their appearance. Energetic steps had to be taken. A hospital was established in the mukhtar's house and staffed by a doctor, staff nurse, two probationer nurses, tamurgi, cook, and male servant. The work of vaccination was pushed on, and in a short time most of the inhabitants had been vaccinated.

Some difficulty was experienced at first. A systematic house-to-house search was instituted. On making an inspection of this sort it is not sufficient merely to enter a house and take the names of those present. The caves, corn bins, tibbin heaps, nooks behind piles of sticks, roofs, gardens, and every hole and cranny had to be searched, and many amusing finds were made.

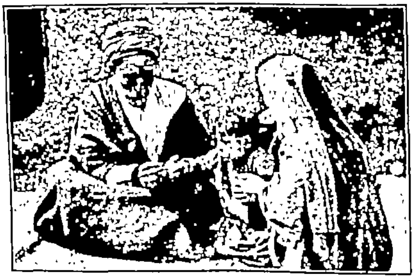
The first lymph which was used proved quite unsatisfactory, only 172 out of 2751 vaccinations showing positive results, and several children developed true small-pox. Fig. 1, taken by Dr. Ayoub from one of those, shows excellently the distribution of the rash. Fresh lymph was obtained from the Government of Egypt, and the difference was quickly apparent. The natives themselves were struck by its greater potency and came forward readily enough even to be done a third time. "It would take on a stone" they said. Vaccination with the "Cairo" lymph marked the turning point in the campaign. No person who was protected thereby developed small-pox. Later a vaccination campaign throughout the whole country was undertaken, and at present it is safe to say that no serious outbreak of small-pox is likely to occur during the next five years.

*The Inoculated Cases.*

Shaheen is a distinguished-looking gentleman of over 50 years of age. Fig. 2, which shows him at work, was taken after his discharge from Hebron prison, where he spent a month as a result of his misguided efforts to limit the spread of the disease. He was the village medicine-man, as had been his father and grandfather before him. In the neighbouring villages and even amongst the Bedouin of the plains to the south he was held to have skill and experience in his profession. His reputation was by no means lessened but rather considerably enhanced by his performance at Dawaimeh and subsequent imprisonment.

Shaheen's method was as follows: As "lancet" he employed the thorns of a shrub (Fig. 3) common in the district. He peeled the thorns with his thumb nail and with this fairly sharp-pointed, useful little weapon he removed the cuticle of a vesicle or pustule of the original case and spread some of the contents on the skin on the back of the web between the forefinger and thumb of the right hand. He then made three little punctures with the thorn point through the variolous matter and skin on which it was spread. After this the thorn was drawn across under the nostrils. This was done, so Shaheen said, in order that the emanation from the variolous matter might be inhaled with the breath and so doubly inoculate the victim. Shaheen told us that when he did not draw blood his inoculation took better. He also told us that he used to conserve his vaccine so that he could inoculate even when he had not an actual case to work from. This he did by rubbing a piece of cloth over the pocks, thus breaking them down and soaking the cloth in variolous matter. The cloth was kept in a bottle full of water which dissolved out the variolous matter and this could be used later as vaccine, or it was allowed to dry and preserved thus. It lasted, he said, for years. His charge for vaccination was an egg or two. Most of the children inoculated were between 1 and 3 years of age, but one was 6 months old and another 8 years. Shaheen was averse to doing children under a year. The wounds produced at the site of inoculation were either punched-out sores big enough to put the top of the little finger into for half an inch, or like ordinary septic sores with scabs on them when I saw them.

Fig. 2.

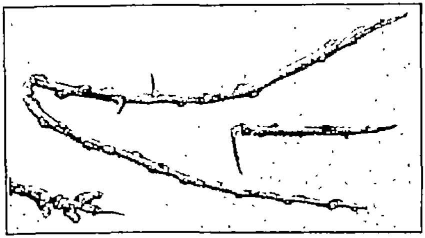


Shaheen at work.

*Variola Inoculata.*

It was difficult to obtain a reliable account of the course of symptoms following inoculation, and we were too late on the scene to observe these ourselves. Roughly it took from four to eight days between inoculation and the appearance of the eruption. Towards the end of that period the patients suffered from malaise, indefinite pains, and loss of appetite. Headache and vomiting, generally present in true small-pox, were not complained of markedly, nor did they say that they had rigors, but stated that fever was present when the eruption appeared. The latter went through the stages of papule, vesicle, pustule, and crust just as in small-pox. Some of the patients were severely ill and out of 116 who had the eruption ten died. The legs, hands, and arms were chiefly affected, as in true small-pox. Most showed from 1 to 35 pocks, but 23 per cent. of cases showed over 200 pocks. This indicates the potency of the strain of virus used by Shaheen, and this is further borne out by the fact that death occurred in 8·6 per cent. of the cases showing eruption and 3·3 per cent. of the number inoculated. The case-mortality in the last epidemic of small-pox in England was about 3 per cent., but in the unprotected it is, of course, much higher than this. The pitting produced by the pocks was less deep than in that of true small-pox. The death-rate for cases inoculated, 3·3 per cent., could not have been so high when the practice was common in England.

Fig. 3.



Thorn of the kind used by Shaheen for inoculating.

It occurred to me that it would be interesting to vaccinate some of the children whom Shaheen had inoculated. Accordingly 27 of the cases which had been inoculated by Shaheen and developed an eruption a year previously were vaccinated. Twelve out of the 27 children vaccinated gave a positive result (roughly 50 per cent.). There is no doubt that if one vaccinated a year later 27 children who had had true variola nothing like that proportion would have been successful.

In general variola inoculata is a mild disease. The death-rate in cases inoculated must have been, I should think, considerably less than 1 per cent. or it would not have gained such popularity after its introduction into England and America. The Dawaimeh cases were much more severe—it is difficult to say why. The climate is mild. Sepsis was not sufficient to account for the high death-rate, and the people are strong and healthy. Shaheen evidently struck a particularly virulent strain of virus.

*Why is Variola Inoculata Milder than Variola Vera?*

That variola inoculata is generally a mild disease, whereas variola vera is a severe one, is possibly due to the fact that the virus, when introduced under the skin, finds itself in an unfavourable medium for propagation. The Chinese method of inoculating small-pox by blowing the crusts into the nose through bamboo pipes also produces a much milder disease than variola vera. Inhalation would not therefore appear to be the normal route of the infection. Neither probably is ingestion, because in the Chinese method it is bound to have taken place in almost every case.[1] Why is it that small-pox when it spreads naturally by contagion or fomites is so much more severe than when inoculated subcutaneously or by blowing into the nose. It is easy to make suggestions. The possibility of an intermediate host in which the virus undergoes development presents itself. But diseases, in the spread of which an intermediate host plays an essential part, do not spread by direct contact. The virus may be spore-forming. But if this were the case Shaheen's dry preserved "vaccine" —that is, cloth soaked in the contents of variolous vesicles, allowed to dry and kept for a long period—would contain the spores, and would therefore be as potent as true small-pox. The same would apply to the Chinese method of inoculation by blowing the dried crusts into the nostrils. These various operations must have been much milder in their effects than true small-pox, otherwise they would have lost their popularity. Shaheen and his Dawaimeh epidemic will, however, have served some useful purpose if it is only to remind us that a "disease" called variola inoculata was once extremely popular, that it took a very fine observer, Jenner, to supersede it with a better "vaccination," and to set us wondering again why small-pox is such a severe infection when acquired naturally, so much less so when its propagation depends on inoculation, and so wonderfully harmless when passed through the calf.

---

[1] Since writing this paragraph I have seen it stated in a French journal that the Armenians were in the habit of producing variola inoculata by eating raisins into which had been pushed the dried crusts of variolous lesions.

My thanks are due to Mr. R. O. Sibley, late chief of the Epidemiological Section of the Department of Health in Palestine, and to Mr. G. W. Stuart, who is in charge of the Laboratory Section, for their suggestions and advice, to Mr. Sibley's successor, Mr. W. J. P. Harkness, and to the two doctors, Ayoub and Mossauba, on whose devoted shoulders fell the heavy load of the routine work.

## THE DOCTOR'S CAR: AN INCOME-TAX SNAG.

UNDER the Finance Act of 1925 a professional man is entitled to claim a deduction from his income-tax for the wear and tear of the car he uses in his work. Several practitioners who applied for this, however, found that they were worse off than if they had refrained, for the assessor, turning up their returns of the last three years, discovered that they had claimed "replacement" when they bought their cars. This allowance he added back, on the principle that they could not eat their cake twice over, and the resulting jump in their average was considerably larger than the amount they were claiming for wear and tear. To take a fictitious but typical example: a doctor buys a car in 1922 for £350, and has this sum allowed him free of tax as a necessary "replacement." In 1925 he claims for wear and tear at 20 per cent. of the written-down value at the beginning of the year, which, allowing 20 per cent. depreciation per annum, will be in the neighbourhood of £45. When the assessor adds back the £350, his average will go up by one-third of this—£117. It would not be much better if the car were only a year old, for a fifth can never equal a third. This is true for all first cars, but when the new car is really a replacement, and has cost more than the amount allowed by the Income Tax Department (cost of old car less sale price) it may be worth the doctor's while to claim. A doctor, for instance, wants to replace his Morris-Cowley, which cost him £280 three years ago, by a car costing £800. He sells the Morris for £91 and is allowed £189 for the replacement. If at the end of the first year he claims £160 wear and tear on the new car, and the £189 is added back, he will get off £160 minus £63; £97.

The owner should, therefore, decide before making his claim which he would rather do, claim or wait. If the car was bought in 1922 it will be out of the picture in the 1926 assessment anyhow, since 1922 is not one of the years on which his average is calculated, and he can claim. If in 1923, then he would do better to waive his claim this year, unless it cost him so much more than his "replacement" allowance that he gains on it. The problem is intimately bound up with the actual depreciation the car undergoes, but it certainly looks as though the "replacement" rebate, when it covers the whole cost of the new car, were more worth having than the diminishing wear and tear allowance.

The best plan of all would be to get a really good car that would last for years with little depreciation. Waiving the wear and tear claim for three years, the owner would then start claiming depreciation on the actual value of his car, calculated not on three years' depreciation at 20 per cent. each, but at the average market price of similar cars. This means, however, a second-hand Rolls or Bentley, which comparatively few can afford. The trouble is that only a really first-class car will actually depreciate at less than 20 per cent. per annum, in spite of the claims of other manufacturers. The car should be a year old originally to avoid the heavy depreciation of the first year. 25 per cent. is the minimum market-price of a car's virginity.

## THE GOLF SWING.

DURING what a humorous custom insists shall be called seasonable weather, the golfer must perforce lose many hours of priceless time, but he need not waste them. He may remember and repent of his sins of the past summer and autumn; and he may seek inspiration for the coming spring. Should he belong to the class of hopeful duffers, we recommend to his notice a book by Dr. James Forrest[1] who by the study of moving pictures, has arrived at very definite ideas about the golf swing. Particularly has he analysed the illusive "wrist action" beloved of golf instructors. The thesis is presented clearly and well and is illustrated by a series of excellent photographs. His theory appeals to us; we have practised it indoors, and, making proper allowances for the restrictions imposed by furniture and electric light fittings, it seems to work. It will be interesting to see how it behaves on the links.

## WHITE WINE ANAPHYLAXIS.

ALTHOUGH wine is responsible for many evils, few would suspect it of containing albuminoids; nevertheless, the experiments of MM. Spillmann and de Lavergne at Nancy, reported in a recent issue of the *Presse Médicale* (1925, No. 81), show conclusively that the cheaper brands of white wine will produce as unpleasant an anaphylactic rash as pork, lobster, and strawberries. Their first subject was a "polyvalent," to whom eggs, bacon, strawberries, and many kinds of fish were poison, and he had already discovered this property of white wine for himself. Red wine, vintage white wine, and champagne were harmless, but a glass of "petit vin" would bring out a rash on his arms and back with the utmost regularity. His discovery was verified in hospital, and in skin-reaction tests checked by controls. White wine, together with egg-yolk, sardine, and bacon, produced a papulo-pruriginous eruption in a quarter of an hour. He was insensitive to ovalbumin and horse serum, and to several other substances that commonly produce anaphylactic symptoms. The controls gave uniformly negative results for all these substances. The explanation is interesting. It appears that red wine contains a large amount of potassium bitartrate, the gradual precipitation of which clears it, but white wine will not clear unless it has added to it a quantity of some kind of glue. Wine merchants are very careful to use in champagne and vintage wine only the minimum quantity necessary, but with cheaper brands one middleman after another may add glue to the same barrel of wine. The substances in use are fish-glue, gelatine-glue, blood-glue and white of egg, as well as certain compositions, and the proportion in the wine may reach one-half of 1 per cent. The blood-glue by itself gave positive anaphylactic results in guinea-pigs, but the wine did not, presumably because the few cubic centimetres injected did not contain an appreciable amount of glue. The fact that a glass of the same wine on an empty stomach cleared up the rash that it had brought out when it was taken with food suggests a justification for the otherwise deplorable apéritif habit. The common reaction of the patient and the two controls to the external application of red wine is reminiscent of the current experiments of Widal on the relative liability of various wines to produce gout. Although this reaction bears all the marks of an anaphylaxis there is no easy explanation of albuminous glue or the like. The offensive constituent in red wine remains an unsolved mystery.

Messrs. Reynolds and Branson, Ltd. (13, Briggate, Leeds), in issuing a wholesale price-list dated January, 1926, call attention to an addition of 15,000 square feet to the floor space of their factories for the manufacture of surgical and scientific instruments, pills, and tablets, and five excellent full-page photographs are given of their present equipment. They announce an arrangement made at 14, Commercial-street, Leeds, for giving demonstrations with ultra-violet light, X ray and other electrical apparatus, including a new pattern of quartz mercury lamp to use current direct from the main, whether alternating or continuous.

# New Researches
## ON THE
# CHEMOTHERAPY OF SYPHILIS.

*Being an Address delivered to the Section of Dermatology of the Royal Society of Medicine on Jan. 21st*

BY C. LEVADITI,
OF THE INSTITUT PASTEUR, PARIS.

IN the Harben lectures, delivered in December, 1923, and subsequently published in the *Journal of State Medicine*, I discussed the therapeutic action of bismuth in syphilis, and that of arsenic administered per os in the form of stovarsol. My later investigations into the action of stovarsol in yaws, amœbiasis, spirillary infections, and malaria will be found in a paper in THE LANCET of Sept. 19th, 1925, p. 593.

In this lecture I shall, therefore, confine myself to a detailed review of the latest investigations into these matters.

### 1. MODE OF ACTION AND OF ABSORPTION OF BISMUTH IN THE TREATMENT OF SYPHILIS.

In a previous paper Messrs. Levaditi, Nicolau, and Mlles. Salgue and Schoen[1] demonstrated that for the destruction of the treponema in the chancre of rabbits treated with basic tartro-bismuthate (trépol) very minute quantities of bismuth are required, so small, in fact, that it was impossible to detect them by the usual methods of titration. Since then, however, Mr. Girard has devised a quantitative method by which 1 "microgramme" (1/1000th of a milligramme) may be estimated in the tissues or body fluids. The following facts relating to the mechanism of the destruction of the spirochæta in the specific lesions have been obtained by this method.

EXP. 1.—Rabbit 81B. Weight=2250 g. Showed two large syphilitic chancres of the scrotum (Truffi's virus); it was given 0·1 g. of trépol per kg. of weight (intramuscularly). On the fourth day all treponemata had disappeared and the lesions were smaller. The animal was killed.

EXP. 2.—Rabbit 91B. Weight=2850 g. Two large chancres of the scrotum. Same treatment, similar results. The animal was killed on the sixth day.

The injected muscles, several organs, and the chancres were examined histologically as well as chemically.

*Histological Examination.*—The histo-chemical method[1] shows the presence of bismuth almost exclusively in the injected muscle. In the muscle the diapedetic process is intense, and reaction phenomena are evident (giant cells, fibroblasts). No lesions of the organs.

*Quantitative Analysis.*

| Rabbit. | Bi content in a gramme of dried substance. | | | | | | |
|---|---|---|---|---|---|---|---|
| | Bi (in microgrammes). | | | | | | Bi (in milligrammes). |
| | Lung. | Spleen. | Liver. | R. testis. | L. testis. | Kidney. | Injected muscle. |
| | µ mg. | µ mg. | µ mg. | µ mg. | µ mg. | µ mg | mg. |
| 81B (killed on fourth day) . | 30 | 48 | 4 | — | 3 | 14 | 17·5 |
| 91B (killed on sixth day) . .. | 10 | 6 | 2 | 2 | 2 | 21 | 8·0 |

*Quantitative Analysis (continued).*

| — | Bi in the chancre. | | | |
|---|---|---|---|---|
| | Rabbit 81B— | | Rabbit 91B— | |
| | in 1 g. of dried substance. | in the whole chancre. | in 1 g. of dried substance. | in the whole chancre. |
| | µ mg | µ mg. | µ mg. | µ mg. |
| Right chancre | 4·5 | 2 | 5·8 | 2 |
| Left chancre | 10·0 | 2 | 4·3 | ±1 |

These results prove (1) that the Bi content of the organs is higher in the rabbit killed on the fourth day than in that killed on the sixth day; (2) that the kidney, lung, and spleen show the largest amounts of Bi; (3) that the lesions contain infinitesimal quantities of Bi. Thus, the destruction of the treponema in the chancres requires amounts of Bi varying between 1 and 2 µ mg. for the whole lesions—that is, between 4 and 10 µ mg. for 1 g. of dried substance. These amounts are hardly larger than those for unreactive tissues, like the liver or testis. From this it follows that the *lysis of the spirochætes occurs under the action of infinitesimal quantities of Bi, no accumulation of the metal taking place in the actual situation where this lysis is brought about.* The destruction of the parasite by Bi appears then as a lytic process, in which mere traces of the metal seem to act as a catalytic agent towards the spirochæticide principles supplied at a given time by the infected organ. As a matter of fact, it is well known that the specific lesions become at length cicatrised, the treponemata preserving their vitality as long as the lesion exists. On the other hand, minute quantities of Hg, As, Bi, and even vanadium, quicken considerably this slow lysis of the parasites. The analogy with certain enzyme processes, which are much accelerated by certain metallic catalysts, becomes thus strikingly obvious.

*Histo-chemical Study of the Mode of Absorption of the Bismuth Compounds.*

After the discovery by Sazerac and Levaditi of the curative action of bismuth in syphilis, it became necessary for the study of its absorption to work out an histo-chemical method for the detection of the metal in the tissues. We have been able to devise such a method, which was reported in the paper already referred to.[1] Our results were as follows:—

*Technique of the Histo-chemical Method* (derived from the analytical method of Leger-Aubry).

Fix with Dubosq-Brasil-Bouin's fluid for 1–5 days. Wash with ordinary water for six hours. Then place the pieces of tissue in the following mixture: potassium iodide, 4 per cent., quinine sulphate, 2 per cent., equal parts, for 6–8 hours at 37° C. Wash with distilled water, alcohol, xylol, and imbed in paraffin. The sections, after removing the paraffin and staining, are immersed in the following mixture: potassium iodide, 2 per cent., quinine sulphate, 2 per cent., equal parts, for two hours at 37° C. The sections are then mounted with or without a counter-stain.[2]

*Delicacy of the Method.*—Applied to the examination of muscles of rabbits injected with solutions of K and Na tartro-bismuthate, varying from 0·01 g. to 0·0001 g., it has proved to be sensitive up to this latter degree (1/10,000), both the tissue in paraffin and the 10 µ section being obviously stained in red. The amount of Bi contained in one single section (5–8 µ) of the injected muscle has been estimated by Mr. Girard to be about 20 microgrammes.

*Experiment.*—Four bismuth compounds have been used: insoluble basic tartro-bismuthate; metallic bismuth in a fine suspension; soluble K and Na tartro-bismuthate; and the proteo-metallic bismuth compound named bismoxyl.[3] We have thus studied the mode of absorption of Bi in all the forms used. The injection was made into the back muscles of infected rabbits showing chancres of the scrotum or into healthy animals. The rabbits were killed from the first day to the thirtieth, and the injected muscle and several organs (liver, kidney, spleen, brain, &c.) were examined for bismuth. Moreover, in the case of several animals, chemical analyses were carried out by Mr. Girard.

---

5R314

[2] As a counter-stain, we prefer the Curtis method.

[3] Levaditi and Nicolau: Annals Inst. Pasteur, 1924, xxxviii., 179.

Our conclusions were the following:—

1. The bismuth compound given by the intramuscular route is absorbed according to its solubility. Whereas the insoluble derivatives remain for a long time in the injected muscle, the absorption taking place slowly and gradually, the soluble compounds, on the other hand, are quickly assimilated, and leave only a very slight residuum. The sudden and massive elimination of these soluble derivatives may bring about in the kidney certain lesions which are not to be found in the animals treated with insoluble bismuth salts, even when the latter were administered in a higher dose.

2. The insoluble bismuth salts, as well as metallic bismuth itself, are not absorbed unless previously rendered soluble within the tissues. The local process of leucocyte proteolysis seems to bring about this solution. The derivatives, thus made soluble, attach themselves to the tissue protein substances and give rise to some proteo-bismuth compounds where the metal is hidden. It is in this form that it travels throughout the body and is eliminated through the kidney. This is demonstrated by the fact that it is impossible to detect the presence of bismuth in the organs (kidney, spleen, and brain) by the histo-chemical method, whereas the analytical process (after a previous destruction of all organic matter) reveals a relatively enormous amount of the metal.

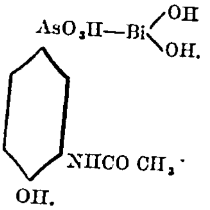
3. The administration of bismuth into the muscle occasions diapedesis, and degenerative and regenerative phenomena, which are more evident with insoluble compounds than with soluble salts or proteo-metallic derivatives. Bismoxyl seems to be, among the latter, that which causes the least local alteration.

4. The part played by phagocytosis in the absorption of bismuth, as we pointed out in 1922,[4] seems more slender than might be supposed at first.[5] The white blood cells, the fixed cells, and the endothelial cells, in fact, the reticulo-endothelial system, act as phagocytes towards the bismuth particles.[6] It does not however, appear that these phagocytic cells allow the bismuth to travel throughout the body. On the contrary, everything seems in favour of the idea that the phagocytes, by fixing the metal, help in the formation of a bismuth "depôt," to which must be ascribed the success of this lasting and efficient therapy of syphilis.

5. This depôt is much greater in the case of insoluble bismuth salts. The muscles retain these salts during several months, supplying the body with relatively minute quantities of an organo-metallic salt, containing hidden bismuth, which are sufficient for the destruction of the treponemata.[7]

## 2. RESULTS OBTAINED WITH BASIC ACETYLOXYAMINOPHENYL ARSINATE OF BISMUTH.

We shall now report our investigations concerning a new compound containing both bismuth and arsenic—namely, basic acetyloxyaminophenyl arsinate of bismuth. When, under certain conditions, the sodium salt of acetyloxyaminophenyl arsinic acid (stovarsol, As content 27 per cent.) and sodium potassium bismuth-tartrate (Bi, 30 per cent.) are brought together, both in concentrated aqueous solution, a white precipitate appears. This precipitate, after several washings, when dried at 50° C., appears as a yellowish-white powder, insoluble in water, but soluble in caustic bases. Chemical analysis proves this substance to be a new compound with the following formula:—



Bi content, 11 per cent. (40·2).
As content, 15 per cent. (14·5).

We have had the action of this compound under investigation since October, 1924. Our results are as follows:—

*Experimental Syphilis.*—The salt has been used as a flocculent suspension either in saline or in oil (10 per cent.). The injection was made into the muscle.

(*a*) Suspension in saline: Bi = 0·0125 g. per c.cm. As = 0·00157 g. per c.cm.

Rabbit 50: Severe lesions, showing numerous treponemata. Weight, 3330 g. Received 1·0 c.cm. per kg.—that is, 0 0125 g. Bi and 0·0015 g. As. Oct. 12th, 1924: Complete healing after four days. No loss of weight. No relapse.

Rabbit 51B: Severe lesions, numerous parasites. Weight, 2700 g. Received 0·5 c.cm. per kg.—that is, 0 0062 g. Bi and 0·00225 g. As. Oct. 23rd, 1924: Complete healing after five days. No relapse.

Rabbit 12D: Severe lesions, numerous treponemata. Weight, 2000 g. Received 0·1 c.cm. per kg.—that is, 0·00125 g. Bi and 0·00015 g. As. Oct. 23rd, 1924: Complete healing after five days. No relapse.

Given in a dose of 0·05 g. per kg. the compound showed no effect. It follows that the *bismuth-arsenic derivative administered as a flocculent suspension in saline proves to be efficient in the cure of experimental syphilis with a dose of 1·5 mg. Bi per kg.* The ratio of the curative to the toxic dose C/T exceeds 1/10 (estimated as Bi).

(*b*) Oil suspension: (10 per cent.: 0·041 g. Bi and 0·015 g. As per c.cm.).

Rabbit 70D: Chancres of the scrotum with numerous parasites. Weight, 2600 g. Received 1·0 c.cm. per kg. (0 041 g. Bi and 0·015 g. As) on Jan. 12th, 1925. The lesions quickly healed.

Rabbit 804A: Severe lesions, many parasites. Weight, 1850 g. Received the same dose (0·041 g. Bi and 0 015 g. As per kg.). Complete healing without relapse after five days.

These findings prove that the arsenic-bismuth compound in an oil suspension exhibits a curative action in experimental syphilis in a dose of 0 041 g. Bi per kg. Our experiments in the mouse nagana and fowl spirillosis demonstrated that the new derivative is also efficient as a preventive and curative agent in the case of these infections (the preventive dose for the fowl corresponds to 0·0036 Bi per kg.).

These results induced us to try the new product in the treatment of human syphilis. The findings of Messrs. Fournier and Schwartz brought full confirmation of our own results. These authors have treated 20 syphilitic patients with chancres or secondary lesions. In spite of the small number of patients and of the short period of time since the beginning of the treatment they are firmly convinced of the high therapeutic value of the product. Nineteen patients received 12 intramuscular injections of 2 c.cm. each of a 10 per cent. oil suspension—i.e., 0·984 g. Bi and 0·36 g. As). A single patient was given two series of ten injections with a month's interval between. The injections were given twice a week. The drug was perfectly tolerated, there was no painful local reaction, and no general reaction. One patient, however, showed, after 12 injections, a mild erythema of the arsenic-erythema type There was no albuminuria and no irritation of the gums. The general condition always remained perfect with no weariness and no loss of weight, as may be observed in the use of a number of bismuth compounds. Probably this favourable characteristic is due to the presence of arsenic, which renders the drug specially useful for patients in poor condition.

[6] Levaditi, Nicolau, Mlles. Salgue and Schoen: Loc. cit.
[7] Levaditi and Girard: C.R. Acad. des. Sciences, 1925, clxxx., 420.

The treponemata disappeared 24 to 48 hours after the first injection; with two patients the sterilisation of the lesions followed the second injection. The cicatrisation was effected very rapidly, as with any of the best bismuth preparations. The drug had a similar action on all general manifestations when they were present. Fourteen patients, who were kept under observation during subsequent months, did not show any relapse.

The effect on the blood reaction was quite obvious. With two patients who had a negative blood W.R. it constantly remained negative, but of 12 subjects with a positive blood W.R. 6 gave a negative result a few days after the beginning of the treatment; with 4 others the blood W.R. was considerably attenuated; and with the 2 last the reaction was not quite so favourably influenced.

From the above findings Messrs. Fournier and Schwartz drew the following conclusions:—

1. The basic acetyloxyaminophenyl arsinate of bismuth is perfectly tolerated and is not handicapped by the inconvenience met with in the use of the ordinary bismuth compounds.

2. The effect on the treponema and on the lesions appears as quickly as it does with the best anti-syphilitic drugs. No relapses are observed.

3. The effect on the blood reactions is quite obvious. A negative test may be obtained after a single series of 12 injections.[8]

These facts have been fully confirmed by Messrs. Nicolau, Doskocil, and Galloway,[9] who have examined the action of the arseno bismuth derivative in the experimental trypanosomiasis of the mouse and rabbit (nagana) and in fowl spirillosis. The compound has proved to have an evident spirillicide and trypanocide effect in vivo

Lastly, further researches by Mr. Popoff [10] furnish another attestation of the above-reviewed facts. This investigation concluded that "the basic acetyloxyaminophenyl arsinite of bismuth has a high antisyphilitic power in the primary or secondary stages of the disease, and even in an old latent syphilis the treponemata disappear and the lesions become cicatrised, while the blood test becomes negative. The change in the blood reaction often takes place some time after the end of the treatment, which proves that the action of the drug is extended over a long period of time. From this point of view it behaves like the bismuth compounds which form a 'depôt' assuring the lasting and deep therapeutic effect of the metal."

### 3. THE ACTION OF GOLD AND PLATINUM AS SPIRILLICIDE AGENTS.

We have investigated the therapeutic power of *gold and sodium thiosulphate* in experimental syphilis of the rabbit. This salt, which has a gold content of 37·1 per cent., was introduced into the therapeutics of tuberculosis by Mollgaard; 0·05 g. per kg. seems to be the maximum tolerated dose when given intravenously. By the subcutaneous route the salt is well tolerated in doses varying from 0·01 g. to 0·03 g per kg; two rabbits received 0·05 g. per kg. One died on the fourth day, the other survived.

*Therapeutic Action* (Truffi's virus and *Sp. cuniculi*).

(*a*) *Intravenous Route.*—Evident curative effect with a dose of 0·05 g. per kg. (0·018 g. pure gold). Spirochætes disappeared on the second day.

(*b*) *Subcutaneous Route.*—The smallest curative dose is 0·02 g. (0·0074 g Au) per kg. (No more spirochætes on the second day; cicatrisation of the lesions on the fourth day; no relapse.) The therapeutic power, although inconstant, was still apparent in a dose of 0·01 g. (0·0037 g. Au) per kg.

(*c*) *Buccal Route.*—Contrary to all expectation, the gold compound, administered by the mouth, brings about the sterilisation of the lesions after two days, and their cicatrisation after 3–5 days, in a dose of 0·20 to 0·50 g. per kg. Given in this way, therefore, gold is absorbed by the digestive mucous membrane.

These findings demonstrate that the gold and sodium hyposulphite has a curative action on the experimental syphilis of the rabbit (Truffi's virus) and on the disease due to *Spirochæta cuniculi.* The ratio C/T, as found by the subcutaneous route, stands around ¼. The compound is efficient when given by the mouth. Further tests have proved that it exerts a real prophylactic action in fowl spirillosis at a dose of 0·01 g. to 0·02 g. per kg.

The results obtained with gold suggested to us the idea of experimenting with platinum in the form of platinum and sodium thiosulphate. This salt has been given by subcutaneous injection in a dose of 0·015 g. to 0·03 g. platinum per kg. to several rabbits infected with *Sp. cuniculi.* In one of these animals the lesions were rapidly cicatrised and the parasites disappeared, two others did not show complete healing, and the lesions were but partially sterilised.

It follows, therefore, that gold, and to a lesser extent platinum, is endowed with spirillicide and treponemicide properties in vivo. These properties are far less marked than those of bismuth. There seems to be a correlation between the atomic weight of these metals and the therapeutic action; bismuth (A. wt.=208) is more active than gold (197·2), which is itself more efficient than platinum (195·2). The form in which gold is given, too, seems to be of great importance. As a matter of fact, the doses being equal or even higher, the potassium and gold chloride and colloidal gold prepared by Mr. Fourneau are totally inactive. We may presume that other metals belonging to the same group (Os, Ir, Ru, Rh, Pd) would have similar properties. Their study is being undertaken.

Such striking results warranted a careful examination of the therapeutic action of gold in human syphilis. The tests have been carried out by Messrs. Fournier and Mollaret.[11] Their conclusions were as follows.

The sodium and gold thiosulphate has an indisputable and rather powerful antisyphilitic action when used in large doses (around 1 g) by intramuscular or intravenous injection. Under those conditions treatment is attended by the disappearance of the treponemata, the rapid cicatrisation of the lesions, and a favourable change in the blood reactions. With small doses the effect is much slower and questionable. The use of this compound is attended by serious inconvenience such as general reactions, cutaneous manifestations, and even the production of albuminuria which constitutes a real drawback to its constant use in the cure of human syphilis; at least, under the form we described.

We must remember, however, that Bruck and Glück,[12] as well as Mario Truffi,[13] had already called attention to the curative properties of potassium and gold cyanide and of gold chloride in human and experimental syphilis.

# REMARKS ON
# MANIPULATIVE TREATMENT.

*Being the Two Opening Papers read at a Discussion at the Medical Society of London on Jan. 25th, 1926.*

I.—BY W. ROWLEY BRISTOW, M.B. LOND., F.R.C.S. ENG.,
ORTHOPÆDIC SURGEON TO ST. THOMAS'S HOSPITAL.

II.—BY R. C. ELMSLIE, M.S. LOND., F.R.C.S. ENG.,
ORTHOPÆDIC SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

## I.—BY W. ROWLEY BRISTOW.

MANIPULATIVE surgery or manipulative treatment should lend itself well to discussion if only for the reason that every year or two brings forth a heated controversy on the subject in either the medical or the lay press, or both. The same well-worn arguments crop up, and, in the lay press at least, a list of distinguished and titled personages who have benefited generally follows, together with letters of gratitude. That this gratitude is given to those who practise bonesetting and are unqualified has led the public to believe that this form of treatment is not included in the armamentarium of the qualified surgeon or practitioner. In these articles, too, all the patients are grateful; failure is relatively unknown, and it is only the doctor who has blundered.

What are the true facts? It is a platitude that adequate treatment necessitates an accurate diagnosis. Diagnosis depends upon an understanding of the anatomy and the pathology of the part affected. Now, is it true that those unqualified practitioners, who have not had the advantage of a general medical education, whose fundamental grounding is necessarily at fault, succeed and the qualified man fails?

### *The Errors of Ignorance.*

I suppose that all of us can recount instances when the patient has failed to benefit in the hands of the unqualified practitioner, and has responded readily and well to orthodox treatment.

In February, 1919, I was consulted by a patient, S., complaining of trouble with the knee. He had had trouble with the other knee and had consulted a bonesetter who had arranged to manipulate. With the patient's consent, I wrote to the bonesetter and told him that I should be glad to witness his manipulation. I wanted to see whether the method used differed in any way from that which I employed. I received a letter saying that the bonesetter regretted that he could not allow me to be present, but that he hoped I would particularly watch the outcome, as this was the type of injury in which "he was pretty uniformly successful." The symptoms were those of recurrent dislocation of the semilunar cartilage, which in my experience was not likely to be cured by manipulation. The patient was not benefited, and a little later I removed the torn cartilage, since when he has had no further symptoms.

Rarely, but very rarely, does manipulation cure a true cartilage lesion—that is, one in which the cartilage is torn and is at times displaced across the joint. Sometimes it may be possible by great force to rupture the so-called bucket handle and allow the torn meniscus to roll up into the inter-condyloid notch; but with the history of repeated recurrence open operation is the safer and more certain procedure. It was interesting to find that in spite of repeated invitations—as I understood them—in the public press the unqualified practitioner was not prepared to allow an orthopædic surgeon to witness his manœuvres.

In April, 1922, a professional footballer, G., was brought to me with a similar history. The same bonesetter had manipulated the knee, and told him he could carry on and play football. At the first attempt the symptoms recurred, and shortly afterwards I removed a torn cartilage from the joint.

In my own practice a similar sequence of events occurs fairly frequently. There is no object in multiplying examples. A less common type of error is when the unqualified practitioner has had a true dislocation to deal with, when a bone has really been out of place, and he has failed to recognise the fact. A child was admitted under my care at St. Thomas's, who had been under a bonesetter for either three or six months, because she walked badly. The manipulative treatment of the spine to which she had been subjected had been ineffectual, because the child was suffering from congenital dislocation of the hip, calling for manipulative reduction. This is an instance of what is perhaps the greatest danger of unqualified practice—namely, the inability to make a correct diagnosis in a simple case.

Within the last week I saw a lady who teaches folk-dancing, and who was suffering from footstrain from overuse. On visiting the bonesetter, she was told that ankles, knees, hips, and spine were all "out," and that two weeks' treatment in his home was essential. She became suspicious and refused treatment, because a certain cure was offered by the same man for her husband who had suffered with osteo-arthritis for many years and was a complete cripple. Moreover, the cure was offered as certain and rapid—it was to take only a week—on her mentioning the fact of her husband's disability. There was apparently no necessity for any preliminary examination.

Another patient, with stiffness of the spine and swelling of the ankles, had spent some weeks and much money on treatment by an osteopath. He was no better. The symptoms were due to a focus of infection, gonococcal in origin, in the prostatic urethra. His symptoms are clearing up under appropriate treatment.

### *Confidence and the Mystic Rites.*

These examples, and they are a few selected at random, are quoted to show that there is reason to believe that the failures of the unqualified are many. It is an unpleasant, although I deem it a necessary task to call attention to the fact. It is not a personal question. Any surgeon whose work and interest lay in bone and joint surgery would have done as I did. I do not wish to imply that we always succeed and that the bonesetter always fails. One man may fail with a patient when another, equally (but no better) armed, and with no greater experience, will succeed. The personal factor is of importance. Many men, with no very obvious qualification, succeed, while the more highly qualified may be failures. I do not mean in the financial sense, but in the sense of succeeding with and of benefiting their patient. Personality counts for much. Experience counts for much. A combination of the two, even when the basis of the work done is empirical, does produce good results. The bonesetter has many successes, but if empiricism rather than knowledge is the foundation on which he works unnecessary errors must creep in.

There is one way in which the unqualified practitioner sometimes scores, and that is because he takes a risk which we are not prepared to take. If we cannot be sure of the diagnosis we must play for safety.

I remember seeing a girl complaining of trouble in the lower part of her back, and I was not certain whether this was due to an inflammatory lesion or not. The X ray left me still in doubt. I saw her in consultation with another surgeon, of great experience, and we were unable to exclude the possibility of her symptoms being caused by disease. We therefore recommended fixation and rest. We heard afterwards that this patient was taken to a bonesetter, who manipulated the spine and cured her.

This is an example of what sometimes happens, and is, I think, bound to happen. That patient is probably going about saying that the profession failed her, and that she was cured by a bonesetter. It is our business to see that this occurs as seldom as may be.

From time to time, when manipulative surgery is discussed by members of the profession, it is hinted that there is something yet to learn—some manipulative art which has been handed down outside the ranks of the regular practitioner, and which he either will not or cannot acquire. The matter is really very simple, and Sir Robert Jones, in his Cavendish lecture, puts it clearly. He says:—

"Let me emphasise the statement that there is nothing which the manipulator does which cannot be more safely undertaken by any practitioner, who possesses a knowledge of the pathology and elementary anatomy of the joint, but he must become familiar with methods of manipulation which are safe and thorough. . . . Let it be fully realised that there are no hidden or mystic rites in the art of bone-setting."

The group of surgeons who are specially interested in bone and joint surgery—and there are over 150 members in the British Orthopædic Association—practice manipulative treatment. I would hazard a guess that year in and year out, the number of patients so treated must run into thousands. This branch of therapeutics is by no means left only to the bonesetters, the osteopaths, and the chiropractors.

A little book entitled "The Medical Follies," written by Dr. Morris Fishbein, a member of the American Medical Association, and sometime editor of its Transactions, has been published recently. The author gives a history of the many forms of quackery and tells of the origin and growth of osteopathy and chiropractic. He summarises very neatly as follows:—

> "It has been said that osteopathy is essentially a method of entering the practice of medicine by the back door. Chiropractic, by contrast, is an attempt to arrive through the cellar. The man who applies at the back door at least makes himself presentable. The one who comes through the cellar is besmirched with dust and grime; he carries a crowbar and he may wear a mask!"

No good purpose will be served in going over old history. We must bear in mind, however, that Wharton Hood in 1871 published a small book in which he dealt quite fully with the subject as appreciated at that time. This book was based on what he had learnt from Hutton, the best known unqualified exponent of manipulative treatment of his period. It is true to say that Wharton Hood's teaching was not well received; but the fact remains that the so-called secrets were laid bare, and the mystery was cleared up.

### *Neglect of Manipulation.*

The methods of manipulative treatment were not absorbed into the general practice of medicine, because the teachers in the medical schools did not recognise their value. There were exceptions, but the statement is fundamentally true—and it is true to-day. The field for manipulative surgery lies largely in the treatment of minor injuries, and to a less extent of chronic joint disease. This is the type of condition which loses its perspective in hospital practice. The graver conditions are those which arrest the attention of the surgeon. Go to what hospital you will, or read the operation lists as posted in the Royal Society of Medicine—you find surgery on the grand scale. There would seem to be no room and no time for adequate attention to be given to those minor disorders, which cease to be minor as soon as the student leaves the hospital and goes out into practice. I do not wish to go outside the bounds of the subject and I do not wish on this occasion to be thought to hold any brief for specialism or segregation, but facts must be faced.

It is not likely that any man can teach and arouse the student's interest in a subject of which he himself has no first-hand knowledge, and the practice of which branch seldom comes his way. If you read in the lay press articles about bonesetters and their cures, you will often notice that the patient has seen previously one or more distinguished members of the profession. You and I know that the choice made was unwise; that the expert whom they consulted was one whose admittedly great ability lay in other fields of surgery. He was not a surgeon whose interest, and therefore of necessity whose experience, lay to any extent in bone and joint surgery.

My own opinion is that it would be wise for those who control medical education to examine their premises, and to consider whether in the huge curriculum which now obtains, sufficient time and care is given to the instruction of the student in these minor ailments which form so large a part of practice. The first point which I venture to suggest as worthy of discussion is that the examining bodies and school councils should have their attention called to this subject of manipulative treatment, and that its principles and practice should be brought more prominently before the student.

For the purpose of this discussion I have left out of consideration the accepted use of manipulative treatment in the correction and cure of deformity, as no good purpose would be served by a discussion from this point of view. For example, manipulation is generally used in the correction of congenital dislocation of the hip, of traumatic dislocations, and for the reposition of fractures. When we consider some of the conditions which are benefited, and inquire into the actual way in which they benefit—what change manipulation brings about—they fall roughly into two main groups. These are the conditions resulting from injury, and those resulting from disease.

### *Conditions Resulting from Injury.*

1. The so-called *internal derangement of joints*, most often met with in the knee, but also occurring in the wrist and the jaw. These joints have one feature in common; they contain an intra-articular fibro-cartilage, and it is sometimes in connexion with an injury to or displacement of this structure that the manipulation does good.

2. *Fibrosis of or about the Capsule: Adhesions.*—The differential diagnosis between this condition and arthritis of the joint must be borne in mind. With arthritis there is restriction of movement in all directions; with adhesions, limitation is noticed in certain movements only. The shoulder-joint provides a common example. Generally, flexion and adduction are free, whilst rotation and abduction are limited. The ankle-joint provides a second example, and the adhesions are commonly limited to the anterior fasciculus of the external lateral ligament. It is in connexion with the results of injuries to the knee-joint that manipulative treatment is perhaps most often discussed.

It has already been suggested that manipulation is sometimes called for because of an injury to the semilunar cartilage, but this is more often necessary when dealing with injuries to the other structures of the joint. Twists and strains of the knee, whilst they may injure the cartilage, more frequently damage the ligaments, and particularly the coronary ligaments. It seems likely that rupture of a few fibres of these ligaments, followed by hæmorrhage and organisation of the clot, brings about adhesions, with the matting together of structures, which account for the symptoms.

The diagnosis of cartilage injury is too often made when there is no real ground for it. In the latter part of the war, practically all the patients with knee-joint injuries were sent to the military orthopædic hospitals labelled as displaced semilunar cartilage. This is not the place or the time to discuss the differential diagnosis, but it is a fact that in the majority the cartilage was intact, and the knee was crippled from the result of injury with adhesions. Many of these patients were rapidly cured by manipulation. It is particularly with this joint that want of accuracy in diagnosis has enlarged the field for the bonesetter.

3. *Fibrosis of Muscle.*—The result of strain or injury is commonly met with in the back, particularly about the lower part of the erector spinæ. Lower backache is common. A voluminous literature has grown up around the lumbo-sacral and sacro-iliac joints. In the United States, if one may judge from the papers published in the journals, it is even more common. Now what are the remedies ordinarily taught to the student? It will depend a little whether the patient, he or she, reaches the medical, surgical, or gynæcological departments from the hospital sorting room. Routine examination reveals no abnormality, and X ray shows a normal spine and normal sacro-iliac joints. A thorough examination may reveal some pain or some restriction of movement on hyperextension or lateral bending of the spine.

Medicines, massage, liniments, electrical treatment, radiant heat, hot air, and the like remedies are tried. Sometimes they succeed, often they fail.

The bonesetter would generally cure such a patient. He would empirically employ forcible manipulation. I agree that the pathology in this instance is not certain, but it seems likely that adhesions have formed in some part of the muscle, or at its attachment to bone or fascia, as the result of injury or infection. Forced manipulation of the spine and pelvis will oftentimes result in complete cure. It is regrettable that such treatment is withheld until the patient has left her doctor or the hospital, and gone as a last resort to an osteopath.

### *Conditions Resulting from Disease.*

It is difficult, if not impossible, to lay down rules or to define exact indications for the use of manipulative treatment in dealing with chronic joint disease. Why, on one occasion, do we treat a stiff shoulder with rest, warmth, and the like, and on another advise forcible manipulation. We rely upon the accuracy of our diagnosis, on our estimation of the pathological state of the joint at the moment. If there is active inflammation, manipulation will lead to disaster; but we shall on occasion employ it with success, if the acute stage is passed, and there be limitation of movement.

Different joints behave differently. Mr. Elmslie is dealing with the subject regionally, and I am leaving the detail to him; but as an instance of what I mean I would recall to you the difficulty of treating stiffness of the fingers and of the metacarpo-phalangeal range. Forced manipulation may be called for, but if it is, then the newly acquired position should be maintained by fixation for a time. Forced manipulation followed by free use results in greater stiffness. On the other hand, we can sometimes restore a useful degree of abduction to a hip-joint, when this movement has been lost as the result of osteo-arthritis, and follow up our manipulation by active exercises.

In addition to appreciating the pathological state of the particular joint, we must form an accurate estimate of the personality of the patient. This is important. Will he be willing to put up with the necessary pain, which the conserving of this newly acquired range will entail? Will he follow the treatment through? It is in dealing with joint disease that we are often called upon to repeat the forced manipulation, perhaps two or three times; at each attempt an added range is gained. The joint will respond to this manœuvre, whilst it would stiffen if we attempted to gain the full range at one sitting. There are other points worthy of discussion—What is the best means of conserving the range of movement gained by forced manipulation? What is the after-treatment? Shall we employ massage, electricity, and exercises, or shall we for a time fix, in our new position, on a splint?

Manipulative treatment is known to us as a profession, but in the multitude of complex disorders, and in the wealth of methods, this simple, homely remedy has been pushed into the background. It is our duty to see that the student of to-day is trained in its use, and that its advantages and limitations are brought before him.

---

## II.—BY R. C. ELMSLIE.

Manipulative methods, as carried out by unqualified practitioners who are variously classed as bonesetters, osteopaths, chiropractors, and otherwise, may be roughly divided into: 1. Manipulations of the affected part—e.g., for adhesions in or around such joints as the shoulder and knee. 2. Manipulations of some other part which is not obviously affected—e.g., manipulation of the spine as carried out by osteopaths. I will take this second group first, because it can be dismissed more easily. In most cases the whole procedure is so obviously irrational that it is difficult

by those who practise it. To manipulate a stiff or disabled knee is reasonable, to manipulate the cervical spine for goitre or for diphtheria, the dorsal spine for gastric ulcer, or any part of the spine for epilepsy, sounds so ridiculous that it is hardly necessary to subject the method to argument or to imagine that these methods will ever be taken up by the medical profession.

The osteopaths have no hesitation in citing medical opinion as favouring their methods. Here, for example, is one quotation from Hilton: "The pain associated with diseased spine is found upon the skin supplied by the nerves which escape from the vertebral canal through the intervertebral foramina." Severe abdominal pain, increased in the erect posture, is traced to "disease with slight displacement between the sixth and seventh dorsal vertebræ." Hilton is obviously speaking of the referred pain of spinal caries, but these words are lifted out of their context by the osteopath, as if they proved that small displacements of the vertebræ can cause visceral disease. Head's areas of referred pain are also quoted by osteopaths as proof of their thesis.

It is perfectly true that massage with passive and active movements of joints and properly regulated exercises can have a considerable effect upon certain visceral diseases. This is largely a medical question, but the medical side of the work of the masseur has been rather neglected by the profession, and it will amply repay some young physician to take the matter up and see whether careful investigation will not prove that there is a greater use for this type of treatment.

The bonesetters who carry out treatment by manipulation of the actual part affected are in some cases, I believe, honest and straightforward. They use methods which are largely the result of actual practice, but which are often well designed, and in the hands of some of them show a certain knowledge of anatomy and pathology. At any rate, the users of these methods gain experience and profit by it; they avoid gross errors of diagnosis, and they meet with results which show a degree of success that we must consider as to some extent merited. Sometimes they make evident mis-statements, which may or may not be deliberate. Thus they will say that there is a bone out of place where there is no bone to be out of place. It is difficult to say whether these mis-statements are due to ignorance or are made deliberately in order to impress their patient.

Other practitioners have less honest methods; their mis-statements are undoubtedly deliberate and exaggerated. Certain bonesetters, if a patient comes with a disability of the ankle, inform him that his ankle, knee, and hip are all out and must be manipulated. Following such a statement rule-of-thumb manipulations are made, which are sometimes successful, but sometimes, particularly in the case of neurotic patients, have disastrous other results.

Thus, I have recently had to treat an hysterical girl, who, having an undoubted disability of the knee-joint, was taken to a bonesetter. The knee and hip were both described as being out, and were manipulated. The knee got right, but the hip then developed a new disability in the shape of a severe hysterical gait; the girl had discovered, as the result of the manipulation, that she had naturally a snapping hip, which now became a real disability. Fortunately, the condition was recent and the patient was readily put right by a simple explanation of the anatomy of snapping hip.

In another case the results were more serious. A small foot disability was treated by manipulation of the lumbar spine and pelvis. The foot got right, but a persistent obsession has arisen, the patient believing that the whole spine and pelvis have now been put out by the manipulator. No amount of persuasion can cure her, and the obsession has become so severe that she must now be classed as a case on the borderline of insanity.

### *Methods of the Unqualified.*

In considering the methods of the unqualified manipulators, particularly whether anything can be points: 1. What are the conditions treated? 2. How do the manipulations cure them? 3. Why do we so constantly see reports of the successes of unqualified manipulators after surgeons have failed? 4. Why do we never see reports of the successes of surgeons?

Mr. Bristow has dealt generally with these questions, and I shall confine myself to a few special points. The reply to the fourth question is largely bound up in the fact that reputable members of the medical and surgical profession do not advertise in the lay papers. Some years ago I treated the stroke of one of the University boats a week before the race for a displaced semilunar cartilage with the knee completely locked in a flexed position. By manipulation under an anæsthetic the joint was put right so quickly that the boy was only out of his boat for 24 hours. The whole incident passed unnoticed, but it may safely be said that had the treatment been carried out by an unqualified bonesetter it would have occupied the central position in most of the papers of the day. Similarly, most of us have treated successfully prominent athletes and footballers, either by manipulation or by operation. In almost any big football match one or more of the players would be found to be minus a semilunar cartilage, which has been removed by some surgeon, leaving a knee strong enough to stand up to the most severe form of athletics. These facts never get publicity, and many people still think that an operation for the removal of a semilunar cartilage leaves a permanently damaged knee.

The third question is also largely one of publicity. It is an undoubted fact that only the successes of the unqualified bonesetter are recorded; their failures remain hidden. The patient often feels that he has been done and has been induced to waste money; but he says nothing of the incident to his friends and often conceals it later when he visits a surgeon. We all meet with these case of failure of the bonesetters; I could recount very many. In some cases there is more than a failure; the patient is made worse. The bonesetter is not necessarily greatly to be blamed. Surgery of all sorts is not an exact science; accurate diagnosis is difficult, and in cases treated by manipulation it is specially so, because we can often only guess at the exact lesion present. Most of us have made the mistake of diagnosing a joint which is suffering from the results of trauma as tuberculous, or a tuberculous joint as traumatic in origin. Moreover, the responsibility of the surgeon is greater than is that of the unqualified man. However experienced he is in manipulative methods he is perhaps rather less inclined to take a risk. Judgment is particularly difficult in treating stiff joints which have resulted from a non tuberculous arthritis. We know that if the arthritis is still active manipulation will almost certainly be a mistake, whereas if it is quiet, manipulation will in certain cases improve movement and diminish pain, but it is difficult to decide the exact stage at which manipulation is advisable. Hence it arises that to attain a regular success in the use of manipulation a large and wide experience in the treatment of disabilities of the bones, joints, and muscles is required. This is to my mind a very strong argument in favour of specialism in surgery. I believe that it is only by giving up certain large sections of surgery—e.g., abdominal and thoracic operations—that a surgeon is able to devote enough time to the treatment of bone and joint conditions to gain a detailed experience in them and thus to be able to judge of the best methods of treatment.

It is quite untrue to say that manipulative methods are not used by the medical profession. I can claim that I personally have used them since I first took up my specialty, and in my school I have followed Paget, Marsh, and Walsham, whose names should be honoured in this branch of surgery. I included a lecture on manipulative methods in my first course of lectures in the medical school and have never ceased to teach upon the subject. The mistake is to think that a surgeon whose chief interest lies in abdominal work is experienced in the whole of surgery. A surgeon who practically never sees or treats a sprain is naturally inexperienced in dealing with the late disability which results from one. The surgical profession is just as capable of carrying out manipulative methods and just as successful as is the unqualified practitioner. I would venture to say that if a strict comparison could be made it would be found that the surgeon, because of his experience of other methods, is the more successful of the two.

### *Indications for Treatment.*

Coming to details of treatment, time will only permit me to give a few examples. Simple traumatic adhesions around joints naturally come to one's mind first. The shoulder, in which rotation is most often restricted, the wrist (flexion), the knee (flexion), and the ankle (plantar flexion and inversion), serve as good examples. In all these the history of onset, the absence of evidence of active arthritis, a careful investigation of exactly which movement is restricted or painful, and an X ray examination are necessary preliminaries.

I have come more and more to the conclusion that careful X ray examination is essential before manipulation. I have had the misfortune to manipulate a tuberculous tarsus even after such an investigation had been declared negative, and I have narrowly escaped manipulating another case in which an X ray showed a very small tuberculous focus in the external malleolus. On the other hand, I have cured by manipulation a number of cases of disability of the ankle, which had been treated for as much as a year as being tuberculous. Ossification in the muscles or in the joint capsule is another discovery which should negative manipulation.

Some years ago I treated a man who, following a football injury, had his knee manipulated four times, twice by a medical man and twice by a bonesetter. Each time the knee became stiffer, until, when I saw him six months after the injury, the joint was perfectly stiff, and an X ray showed large plaques of bone in the vastus internus and in the inner side of the capsule. Resting the joint for a year on a splint restored mobility. I have since seen a second case of ossification in the capsule of the knee-joint, manipulated by the same bonesetter, again with the result that the knee was rendered much worse.

In manipulating a joint for adhesions it is necessary beforehand to determine exactly what movement is restricted or painful. Thus, I have seen a painful hip in which internal rotation in the flexed position was the movement restricted; and knees which require external rotation in full flexion and ankles which require plantar flexion and inversion are common.

Derangements of joints due to damage and displacement of an intra articular meniscus constitute perhaps the most important group of cases in which manipulation is practised. Such a derangement may occur in the temporo-mandibular joint.

I saw some time ago a young woman who awoke one morning and found that she could not open her mouth. There was much pain in the left temporo-mandibular joint and the chin was deviated slightly to the left. After investigation of the teeth and jaw by an X ray an anæsthetic was administered and the jaw opened with a gag whilst the chin was lifted and the angle of the jaw brought forward. A loud snap occurred, and the jaw opened. On recovery from the anæsthetic it was found that full movement was present.

### *The Knee and Foot.*

We all practise manipulation for derangement of the knee. In a clear case of locking of the joint resulting from injury to a semilunar cartilage with displacement occurring for the first time, I consider that such manipulation is the correct treatment. Often the disability will not recur. But this is only one of at least 12 possible causes of derangement, and in many cases the exact diagnosis is difficult. Manipulation will also cure cases of adhesions, of nipping of a synovial fringe, and some cases of partial locking due to an incomplete marginal tear of a cartilage, probably by completing the tear and displacing the cartilage into the intercondylar notch.

But manipulation cannot be expected to cure loose bodies, injuries of the crucial ligaments, cysts of the synovial membrane, or recurrent dislocation of the patella. Nor will it cure a complete bucket-handle split of the cartilage with recurrent displacement and locking. Accurate diagnosis of the exact lesion present is necessary, and it is to be feared that it is often not made. Diagnosis can only be improved by keeping very careful records of the history and signs and comparing them with operation findings.

A further point requires emphasis. At the present time an exploration of the knee-joint carried out by a competent and experienced operator is a perfectly safe proceeding. It is, in my opinion, often safer than a violent manipulation carried out in the dark with an incomplete preliminary diagnosis. Moreover, it promises a certain cure if a definite lesion is found, and this cannot be said of a manipulation. Therefore, whilst I believe that there are many cases in which we ought to manipulate and in which we may reasonably expect a cure by this method, I maintain that in many operation is essential, and in many others operation is the safest method. Failures after manipulation are extremely common, although they do not obtain publicity. Almost every case of derangement of the knee upon which I operate has been previously subjected to manipulation. I have operated upon as many as three in one week in which recurrence of symptoms had occurred after a bonesetter's manipulation.

I must say one word about the foot, which is responsible for many of the successes of bonesetters. Owing to the nature and fitting of our shoes the movements of the foot, and particularly of the toes, are habitually cramped, and the intrinsic muscles go out of action. It is particularly so in women, because they favour a short shoe and a high heel, often so cut as to throw the whole weight on to the forepart of the foot. The result is the loss of the metatarsal arch with clawing of the toes, which become hyperextended at the metatarso-phalangeal joints and flexed at the distal joints. The bonesetter announces that the toes are dislocated, and by manipulating them restores their mobility and gives comfort to the patient. It was formerly my practice to manipulate many of these cases under an anæsthetic and with great success. I have found, however, that with due training a good masseuse can cure this condition easily in a few treatments. The work of the massage profession, which was for long stereotyped on Swedish lines, has improved enormously during recent years as the result of close coöperation with the surgical profession. This is particularly true of the treatment of injuries. In fact, very often a good masseuse knows more of the practical treatment of injuries than the medical man. The student and the house surgeon learn far too little of this branch of treatment and gain too little experience in it. If we wish to avoid the reproach that the medical profession pays no attention to manipulative surgery, we must find room for a greater amount of teaching, and for better teaching, of this branch of surgery. The material is there; the methods are used and practised; the men are there to teach, if they are only given an opportunity.

---

LONDON CLINICAL SOCIETY.—The inaugural meeting of this new medical society will be held on Thursday, Feb. 18th, at the London Temperance Hospital, Hampstead-road, N.W., when Sir W. Arbuthnot Lane will give an address entitled Is Civilisation a Failure? All medical men and women will be welcome at this meeting. The society has been founded mainly with the object of bringing together the medical men and women resident in the north, north-west, and west-central districts of London, but membership is open to all registered medical men and women. The annual subscription is at present fixed at 5s., with an entrance fee of the same amount. The following are the officers of the society: President, Mr. Herbert J. Paterson; vice-presidents, Dr. Soltau Fenwick and Dr. A. J. Clarke; hon. treasurer, Dr. E. A. Gregg; hon. secretary, Dr. Philip Figdor, 150, Harley-street, W. 1, from whom further particulars can be obtained.

---

# A STUDY OF THE EFFECT OF PASTEURISATION ON THE INFECTIVITY OF THE MILK OF TUBERCULOUS COWS.

BY R. G. WHITE, M.B. GLASG.

(*From the Bacteriological Department, Lister Institute.*)

THE literature on the subject of the viability of the tubercle bacillus, when acted upon by heat at various temperatures and for various times, is full of contradictory statements, and this is especially the case in connexion with the vexed question of the effect of pasteurisation on the infectivity of tubercle-infected milk. The literature for the period from 1882 to 1907 on so-called death-point determinations of tubercle bacilli is summarised by Rosenau (1908), and from his own work on the subject, experimenting with milk heavily infected with virulent cultures, he arrived at the following conclusion:—

> "From these experiments it is evident that tubercle bacilli in milk lose their infective properties for guinea-pigs when heated to 60° C. and maintained at that temperature for 20 minutes, or to 65° C. for a much shorter time."

In the course of a controversy on this subject in the German literature (1908–10) Van der Sluis (1909) summarised the results of investigations up to the year 1909, and agreed with de Jong (1908) that one hour at 80° C. was necessary to kill tubercle bacilli in milk; this also was the opinion of Basenau (1909). In these experiments both naturally and artificially infected milks were used. Forster (1909, 1910) criticised this work and came to the conclusion that tubercle-infected milk when heated to a temperature of 65° C.–66° C. and held at this temperature for 15 minutes was no longer capable of giving rise to tuberculous infection in guinea-pigs. As a result of investigations carried out in America, the U.S. Department of Agriculture since 1910 has recommended that milk be heated to 145° F. and held for 30 minutes.

A table giving the results of various inquiries on this subject appears in a report by Delépine (1914) to the Local Government Board. Campbell Brown (1923), as the result of his own investigations, agrees with the results of the majority of the various workers quoted in this table which he also reproduces. He found that a temperature of 60° C. and a period of "holding" of 20 minutes was sufficient to prevent milk infected with laboratory-grown cultures of tubercle bacilli from infecting guinea-pigs when inoculated subcutaneously.

### *Object of Present Inquiry.*

The object of this inquiry was to determine whether or not the milk of tuberculous cows is rendered non-infectious for guinea-pigs when the milk is heated to 145° F. (approx. 62·5° C.) and held at this temperature for a period of 30 minutes—the milk being afterwards rapidly cooled. The temperature (145° F.) and the time (30 minutes) had been chosen as being the limits which should not be exceeded if the nutritive qualities of the milk were not to be materially altered, and were in accordance with the findings of Rosenau and the recommendations made by the American Government for the commercial pasteurisation of milk. Objection has been taken to the use of artificially infected milk in such tests as those carried out by Rosenau, and one of the main objects of the present inquiry was to carry out tests with naturally infected milk.

### *Nature and Extent of Infection of Milk Used.*

Great difficulty was experienced in obtaining a suitable cow for the purposes of the tests, so that the first four tests were carried out with artificially infected milk. The first test was made with milk to which had been added a weighed quantity of a laboratory-grown culture of tubercle bacilli. The strain was kindly supplied by Dr. Schütze, of the Lister Institute, who had recently recovered it from a monkey dead of the infection. The culture was the second subculture after separation of the organism, and was highly virulent for guinea-pigs. This test was carried out in test-tubes (eight) each containing 4·5 c.cm. of infected milk; these formed a series of 1 in 10 successive dilutions containing approximately from 2500 million T.B. in the first tube to 25 T.B. in the last tube of the series. For the second test 15 mg. of two stock laboratory strains of T.B. were used to infect 1 litre of milk. These strains, both bovine, were kindly supplied by Dr. St. John Brooks from the National Collection. In this test the milk contained approximately 15 million T.B. per c.cm.

In order to simulate more closely the conditions as they exist in naturally infected milk, for the third and fourth tests, the milk to be tested was emulsified with ground-up caseous matter and glands from guinea-pigs infected with milk from the first of the two experimental cows used in connexion with the tests. The artificially infected milk for these two tests (Nos. 3 and 4) was found by inoculation into guinea-pigs to contain at least 10,000 infective T.B. per c.cm. The remaining tests were carried out with naturally infected cow's milk.

For these experiments the first cow obtained, although showing distinct evidences of tuberculous mastitis and giving a positive tuberculin reaction, yielded a milk which on microscopical examination of the centrifuged deposit and cream showed the presence of acid fast bacilli on two only out of many examinations, and after prolonged search. In order to obtain some idea of the extent of the infectivity of the milk, daily tests were carried out for a period of a week, guinea-pigs being inoculated with graded dilutions of each day's yield of milk, and the result was practically constant—viz., 0·1 c.cm. gave a positive and 0·01 c.cm. an invariably negative result. Although a more heavily infected milk would have been desirable, still, owing to the difficulties which had been experienced in obtaining a suitable cow, it was decided to proceed with the tests. Shortly afterwards, however, the secretion of milk stopped and the cow had to be slaughtered. The tissues of guinea-pigs which had been infected with the milk of this cow were used in two of the tests (Nos. 3 and 4).

Ultimately a second cow was obtained; this cow also showed clinical signs of tuberculous mastitis and gave a positive tuberculin reaction, and on microscopical examination of the centrifuged milk acid-fast bacilli were constantly found. Inoculation of guinea-pigs with dilutions of the milk gave a positive result with 0·0001 c.cm. and a negative with 0·00001 c.cm. The remaining tests were carried out with the milk of this cow—the milk containing as a minimum 10,000 infective doses of tubercle bacilli per c.cm. In order to allow for any variation in the number of tubercle bacilli passed daily in the milk, the litre of milk to be tested was usually taken from a mixture of more than one day's yield of milk. For two of the tests, in order to obtain a still more heavily infected milk, daily samples of the cow's milk (2 pints) were centrifuged on arrival at the laboratory, and the cream and deposit separated and stored in the cold room. For one of these tests (No. 9) the cream and deposit of seven days' samples were emulsified in a mortar and made up to a litre with the separated milk—the resulting emulsion being used for the test. For the other test (No. 10) six days' samples were similarly treated. In the latter case guinea-pigs were inoculated with successive 1 in 10 dilutions from 0·1 to 0·000001 c.cm. and all were found to be infected so that the milk in this case contained at least 1 million infective doses of tubercle bacilli per c.cm.

### *Method of Pasteurisation: Technique Employed.*

As regards the details of the method of pasteurisation, all the tests with the exception of the first were carried out on the same lines:—

After taking samples, for purposes of control, of the milk to be tested, 1 litre of the milk was poured into an earthenware pot. The type of pot used was a domestic cooking vessel bought in one of the larger stores and labelled "The Gourmet Boil'a, Challis patent No. 7"; it is slightly raised on three legs and the wall is about a quarter of an inch thick. This pot containing the milk to be tested was placed in a pan of water at about 80° C., and by means of a ring burner the water was kept near the boiling-point in order to raise the milk to the desired temperature (62·5° C.) as quickly as possible. The hot-water pan was covered with a lid through holes in which passed a mechanical stirrer and two thermometers—the stirrer and one of the thermometers passed into the milk and the other thermometer into the water in the outer chamber. To allow of the passage of the stirrer and thermometer into the milk a tin lid pierced with two holes replaced the earthenware lid supplied with the Gourmet Boil'a. During the heating the milk was constantly but gently stirred. The time taken to raise the milk to 62·5° C. was about eight minutes. As soon as this temperature was reached the Gourmet Boil'a was removed and placed in a constant temperature copper boiler—regulated at 62·5° C. By means of a similar arrangement to that used in the earlier or "pre-heating" stage, the milk was kept in gentle motion and with the aid of two thermometers the temperature of the milk in the container and the water in the copper boiler could be read off. After 30 minutes "holding" at the temperature of 62·5° C. the milk container was removed and rapidly cooled to about 30° C. by placing it in a bucket of ice and water, the stirring at this stage being carried out by hand.

In the first test the dilutions of infected milk in test-tubes were heated rapidly in an ordinary water bath to 62·5° C. and maintained at this temperature for 30 minutes. In this test the milk was not mechanically stirred. Any variation in the general method of carrying out the test as, for example, in test No. 2 where the milk was kept in motion by a current of air, is given in the detailed description of the various tests.

*Manipulation of Pasteurised Milk.*—In order to test as large a volume as possible of the pasteurised milk, the whole litre of milk after pasteurisation was spun in a high-speed centrifuge and the cream and deposit were used for inoculation.

### *Technique of Animal Tests.*

For the results of the tests reliance was placed entirely upon animal experiments.

Guinea-pigs were inoculated subcutaneously into the fold of the groin and all surviving animals were allowed to remain for periods up to three months before being killed and examined. With one exception, a series of control animals was inoculated in every test, four or five guinea-pigs receiving respectively 1·0 c.cm. and successive 1 in 10 dilutions of the milk, from 0·1 c.cm. to 0·001 c.cm. or 0·0001 c.cm. In the remaining tests, which were each carried out with 1 litre of milk, four or five guinea-pigs were inoculated, two with 2·0 c.cm. to 4·0 c.cm. of the cream emulsified in a small quantity of the separated milk, and the remainder with all the deposit divided amongst them. The total deposit was made up to 6·0 c.cm. with separated milk and guinea-pigs were inoculated—either three guinea-pigs with 1·0, 2·0, and 3·0 c.cm. respectively, or two guinea-pigs with 3·0 c.cm. each of the emulsified deposit.

In the earlier tests cultures on glucose-agar and Dorset medium were made but, owing to the invariable presence of contaminating organisms, the use of cultures was discontinued. Autopsies were made on all the animals, and where there appeared to be any possibility of doubt, a second guinea-pig was inoculated from these, as in the case of certain animals with abscesses showing the presence of acid-fast bacilli of the butter bacillus type. As a general rule, the post-mortem findings were absolutely definite, the animals inoculated with the raw milk were either dead by the sixth week or were killed at this date, and the post-mortem findings were typical. In the case of the animals inoculated with the cream and deposit of the milk after pasteurisation (with the exception of one positive finding, which is dealt with later), and the guinea-pigs which were infected with a butter bacillus, these animals had grown considerably and had put on fat, so that a post-mortem examination might not have been considered necessary. It was, however, carried out in every case.

### *Details of Tests.*

SERIES 1.—*Experiments with milk infected with T.B. cultures.*

TEST 1.—Carried out in test-tubes: 5 mg. of a glycerine-agar culture of a virulent strain of tubercle bacilli emulsified in 1·0 c.cm. saline and a 1 in 10 dilution made by adding it to 9 c.cm. milk. From this successive decimal dilutions were made, and by halving the contents of each tube two series of dilutions were obtained—each series consisting of eight tubes containing 1·5 c.cm. of milk in each tube and with approximately 2500 million T.B. in the first and 25 T.B. in the last tube. One set of these tubes was heated as described and the other set retained for purposes of control.

(1) *Control animals*, inoculated with milk before pasteurisation. Four guinea-pigs inoculated with 3·0 c.cm. of the contents of the first, fourth, sixth, and seventh of the series of unheated tubes (the last and weakest of these containing approximately 160 T.B.).

*Result.*—All ultimately found to be infected.

(2) *Test animals*, inoculated with milk after pasteurisation. Eight guinea-pigs inoculated with 3·0 c.cm. of the contents of each of the heated tubes (the highest of these doses containing approximately 1600 million T.B.).

*Result.*—All proved to be non-infected.

TEST 2.—Carried out in the improvised pasteurisation plant described—1 litre of milk used for the test; stirring carried out by passing a current of air through the milk; with this exception procedure as described. Subcultures on Dorset medium of two bovine strains of tubercle bacilli used to infect 1 litre of milk—15 mg. of culture being used.

(1) *Control animals*, inoculated with milk before pasteurisation. *A series of successive 1 in 10 dilutions of* the infected milk made, and of these five dilutions (1 c.cm. of each) inoculated into guinea-pigs (the last and weakest of these containing approximately 1 million T.B.).

*Result.*—All in due course found to be infected.

(2) *Test animals*, inoculated with milk after pasteurisation. Milk centrifuged and cream and deposit separated; 2 c.cm. and 5 c.cm. of the cream inoculated into two guinea-pigs and all the deposit—divided into 1/6th, 2/6th, and 3/6th, inoculated into three guinea-pigs.

*Result.*—All animals non-infected.

SERIES 2.—*Experiments with milk infected with tuberculous glands.* (Proved by animal inoculation—see below—to contain at least 10,000 infective T.B. per c.cm.)

TEST 3.—1 litre of milk infected with the ground-up glands (caseous lymphatic glands and spleen) of guinea-pigs infected by subcutaneous inoculation of the milk of first experimental cow. The guinea-pigs showed extensive tuberculous infection. The glands were ground up in a mortar and an emulsion *made with part of the cream* separated from the litre of milk with which the experiment was to be carried out. Emulsion made as homogeneous as possible in large mortar and remainder of milk added and again emulsified. The artificially infected milk was then poured into the Gourmet Boil'a through a muslin cloth, similar to that used commercially for straining milk, to remove the grosser fragments of tissue.

(1) *Control animals*, inoculated with milk before pasteurisation; 1·0 c.cm. and dilutions of 0·1, 0·01, 0·001, and 0·0001 c.cm. of the infected milk inoculated subcutaneously into guinea-pigs.

*Result.*—All in due course showed marked tuberculous infection.

(2) *Test animals*, inoculated with milk after pasteurisation. Five guinea-pigs inoculated respectively with 2·0 c.cm. and 4·0 c.cm. of the cream and 1/6th, 2/6th, and 3/6th of whole deposit of the centrifuged *milk after passing through the* pasteurisation process.

*Result.*—Guinea-pig receiving 2/6th of the deposit dead of sepsis two days after inoculation, remaining animals killed three months after date of inoculation and showed no signs of tuberculous infection.

*TEST 4.—1 litre of milk* infected with ground-up glands of tuberculous guinea-pigs and procedure as in former test.

(1) *Control animals*, inoculated with milk before pasteurisation; 1·0 c.cm. and decimal dilutions to 0·0001 c.cm. inoculated into guinea-pigs.

*Result.*—All in due course showed typical tuberculous lesions.

(2) *Test animals*, inoculated with milk after pasteurisation. After centrifugalisation of *pasteurised* milk *two guinea-pigs* each inoculated with 5·0 c.cm. of the cream.

*Result.*—One dead of sepsis, the other killed and examined *65 days after inoculation.* No signs of tuberculous infection found.

The deposit of 5/6th of the litre of milk (1/6th was lost by the breaking of one of the centrifuge pots) inoculated in the proportion of 1/6th, 2/6th, and 3/6th *into* three guinea-pigs; these animals examined 65 days after inoculation.

*Result.*—Found to be non-infected.

TEST 1 (*a*).—Carried out in order to get some idea of the numbers of infective tubercle bacilli left in the milk after the first stage—i.e., after it had been raised to the temperature of 62·5° C. Samples were taken of the milk as soon as the container was removed from the pre-heater and placed in *the holder, the milk having been at a temperature of* 62·5° C. for less than five minutes—possibly only for three minutes. Five guinea-pigs were inoculated respectively with 1·0 c.cm. and decimal dilutions to 0·0001 c.cm.

*Result.*—All in due course gave a negative result.

SERIES 3.—*Experiments with naturally infected milk.*

TEST 5.—1 litre of milk from one day's yield of experimental cow used.

(1) *Control animals*, inoculated with milk before pasteurisation; 1·0 c.cm. and decimal dilutions to 0·0001 c.cm. of unheated milk inoculated into guinea-pigs.

*Result.*—After six weeks all proved to be infected.

(2) *Test animals*, inoculated with milk after pasteurisation. Five guinea-pigs inoculated—two with cream and three with the deposit divided amongst them as in former test.

*Result.*—Four animals after two and a half months gave a negative result and the fifth, which had received 4·0 c.cm. of the cream, died of sepsis.

TEST 6.—1 litre of a mixed sample of four days' yield *of the experimental cow's milk used.*

(1) *Control*, before pasteurisation. Five guinea-pigs inoculated with 1·0 c.cm. and decimal dilutions to 0·0001 c.cm. of the unheated milk.

*Result.*—After six weeks all proved to be infected.

(2) *Test, after pasteurisation. Five guinea-pigs* inoculated —two with cream and three with the deposit divided amongst them.

*Result.*—Four animals after 62 days showed no evidence of tuberculous infection; the fifth, which had received 4·0 c.cm. of cream, died of sepsis.

TEST 7.—1 litre of mixed sample of five days' yield of the experimental cow's milk used.

(1) *Control*, before pasteurisation. Four guinea-pigs inoculated respectively with 1·0 c.cm. and successive decimal dilutions to 0·001 c.cm. of the unheated milk.

*Result.*—After five weeks all proved to be infected.

(2) *Test*, after pasteurisation. Four guinea-pigs inoculated —two each with 3·0 c.cm. of the cream *and two each* with half of the deposit.

*Result.*—Of the former, one gave a negative result and *the other died of sepsis four days after inoculation.* Of the latter two, those which received deposit, one died five weeks after inoculation and showed distinct signs of tuberculosis, the other was killed and examined two and a half months after inoculation and showed no signs of tuberculous infection, the animal having increased in weight and put on fat.

TEST 8.—1 litre of mixed sample of six days' yield of the experimental cow's milk used.

(1) *Control*, before pasteurisation. Four guinea-pigs inoculated respectively with 1·0 c.cm. and successive decimal dilutions to 0·001 c.cm. of the unheated milk.

*Result.*—After five weeks one died of advanced tuberculosis, and the other three were killed and examined and found to be infected.

(2) *Test*, after pasteurisation. Four guinea-pigs inoculated—two each with 3·0 c.cm. of the cream and two each with half of the deposit.

*Result.*—No signs of tuberculosis were found in these pigs when killed and examined two and a half months later.

TEST 9.—1 litre of mixed sample of seven days' yield of the experimental cow's milk used.

*(1) Control*, no control *animals inoculated.*

(2) *Test*, after pasteurisation. Four guinea-pigs inoculated —two each with 3·0 c.cm. of the cream and two each with half of the deposit.

*Result.*—Three months after inoculation two of former and one of the latter killed and examined and showed no signs of tuberculous infection; the fourth animal died of sepsis.

TEST 10.—2 pints of each day's yield of milk *for* six days centrifuged; cream and deposit separated and kept in the ice-room. The collected samples of cream and deposit mixed for the test and made up to 1 litre with the *separated* milk.

(1) *Control*, before pasteurisation. Five guinea-pigs inoculated, each with 1·0 c.cm. of successive decimal dilutions representing from 0·01 c.cm. to 0·000001 c.cm. of the original milk.

*Result.*—All in the course of four to six weeks gave a positive result.

(2) *Test*, after pasteurisation. Four guinea-pigs inoculated—two each with 3·0 c.cm. of the cream and two each with half of the deposit.

*Result.*—The two former were killed three months after inoculation and gave a negative result. The two latter died of sepsis three days after inoculation.

TESTS 11, 11 (*a*), 11 (*b*).—For these tests three separate litres of a mixed sample of five days' yield of the experimental cow's milk used—1 litre for each test. The three tests were carried out as before with the exception that the period of "holding" was varied as follows:—

11 .. .. Milk held for 30 min. at 62·5° C.
11 (*a*) .. .. " " 20 " "
11 (*b*) .. .. " " 10 " "

(1) *Control*, before pasteurisation. Five guinea-pigs inoculated, each with 1·0 c.cm. of successive decimal dilutions representing 0·01 c.cm. to 0·000001 c.cm. of the mixed milk.

*Result.*—The first three gave a positive result, whilst those inoculated with dilutions of 0·00001 c.cm. and 0·000001 c.cm. were not infected.

(2) *Test* 11—i.e., after milk was held for 30 minutes. Four guinea-pigs inoculated—two each with 3·0 c.cm. of the cream and two each with half of the deposit.

*Result.*—No evidences of any tuberculous infection found in these animals.

*Test* 11 (*a*)—i.e., after milk was held for 20 minutes. Four guinea-pigs inoculated—two each with 3·0 c.cm. of the cream and two each with half of the deposit.

*Result.*—The two former gave a negative result whilst the two latter died of sepsis.

*Test* 11 (*b*)—i.e., after milk was held for 10 minutes. Four guinea-pigs inoculated—two each with 3·0 c.cm. of the cream and two each with half of the deposit.

*Result.*—The two former gave a negative result, whilst the latter were both infected with an acid fast organism of the butter bacillus type; neither these animals nor the guinea-pigs inoculated with material from them gave any signs of a tuberculous infection.

### *Summary of Results.*

All control animals, inoculated with dilutions of the unheated milk, gave a positive result, except where the dilutions were taken to a point beyond the infective dose. The following table gives the results of the test guinea-pigs—those which had been inoculated with the milk after it had been subjected to the pasteurisation process described either as in the first test in the form of dilutions of the infected milk, or as in the other tests with the cream and deposit of the centrifuged milk.

Series I includes tests on artificially infected milk (T.B. cultures).

Series II. includes tests on artificially infected milk (caseous lymphatic glands, &c.).

Series III includes tests on naturally infected milk (experimental cow's milk).

Series IV. includes tests where milk was held for periods of less than 30 minutes).

| Series. | Test. | G.P. inoculated and total. | Negative. | Positive. | Died of other infections. | Series. | Test | G.P. inoculated and total. | Negative. | Positive. | Died of other infections. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| I. | 1 | 8 | 8 | — | — | III. (cont.) | 8 | 4 | 4 | — | — |
| | 2 | 5 – 13 | 5 | — | — | | 9 | 4 | 4 | — | — |
| | | | | | | | 10 | 4 | 2 | — | 2 |
| II. | 3 | 5 | 5 | — | — | | 11 | 4 – 30 | 4 | — | — |
| | 4 | 5 – 10 | 4 | — | 1 | | | | | | |
| | | | | | | IV. | 4 (*a*) | 5 | 5 | — | — |
| III. | 5 | 5 | 4 | — | 1 | | 11 (*a*) | 4 | 2 | — | 2 |
| | 6 | 5 | 4 | — | 1 | | 11 (*b*) | 4 – 13 | 3 | — | 1 |
| | 7 | 4 | 2 | 1 | 1 | | | | | | |

It will be seen that out of a total number of 53 guinea-pigs inoculated with artificially infected and naturally infected milk, after it had been heated as described to 62·5° C. and held at this temperature for 30 minutes, six died either as the result of sepsis or from infection with an organism of the butter bacillus type. Of the remaining 47 animals, 46 gave a negative result and one showed a definite tuberculous infection. With regard to this one positive result it is to be noted that the whole deposit of the litre of milk, after centrifugalisation, was inoculated into two guinea-pigs—each receiving one-half of the deposit. As the other animal of the pair showed absolutely no signs of infection and the one referred to was unmistakably positive—the possibility of an accident cannot be overlooked. Every care was taken with regard to using separate pipettes, syringes, &c., also with the labelling and care of the guinea-pigs, but as each test took about three hours to carry out and as each detail as to temperature, &c., had to be personally controlled, it is possible that an accident may have occurred. This result, which proved to be the one exception in the tests, I am therefore inclined to interpret in this light.

With regard to the three special tests (Series IV.) these were carried out as a matter of interest and were apart from the main line of investigation. It was considered that the sterilisation of the milk so far as tubercle was concerned would no doubt follow the same laws as are found to hold in the case of disinfection with chemical compounds, and that the death point of the organism would follow a logarithmic curve when plotted out as a function of time and temperature. A detailed investigation on these lines was beyond the scope of this inquiry, but by keeping the temperature constant it was hoped that varying the time might give some indication of the rate of change in the milk from an infective to a non-infective condition. The tests carried out were too incomplete to enable definite conclusions to be drawn, but it is worthy of note that in the case of the first of the special tests (Test No. 4 (*a*)), where the milk was tested shortly after it had been raised to 62·5° C. (with less than five, possibly three, minutes holding at this temperature), five guinea-pigs inoculated respectively with 1·0 c.cm. and successive decimal dilutions to 0·0001 c.cm. all gave a negative result. This milk before pasteurisation was shown by control inoculations into a series of guinea-pigs to contain a minimum of 10,000 infective doses of T.B. per c.cm. Unfortunately, larger doses than 1·0 c.cm. were not inoculated.

As to the other two special tests (Nos. 11 (*a*) and 11 (*b*)) in which the milk (1 litre) was heated to 62·5° C. but held for shorter periods than 30 minutes—viz., 20 minutes in the case of the first test and 10 minutes in the second—the results were complicated by the presence of extraneous organisms. It is of interest, however, to note that no evidences of a tuberculous infection were found in the two surviving guinea-pigs out of four inoculated in the first nor in three out of four inoculated in the second of these tests.

### *Conclusions.*

Experiments have been carried out with naturally infected milk from cows with tuberculous udders, with milk contaminated with cultures of tubercle bacilli, and with milk to which ground-up caseous tuberculous glands have been added. The method employed was to raise the temperature of the milk to 62·5° C. and to keep it at this temperature for 30 minutes. The results obtained by inoculating such pasteurised milk into guinea-pigs have shown clearly that pasteurisation carried out under these conditions ensures a non-infective milk so far as *B. tuberculosis* is concerned.

I am greatly indebted to Prof. C. J. Martin and Prof. J. C. G. Ledingham for their advice and suggestions, and to Mrs. M. M. Barratt for much valuable help.

### A CASE OF

# PERNICIOUS ANÆMIA OF APLASTIC TYPE,

### WITH PHAGOCYTOSIS OF ERYTHROCYTES.

By L. E. H. WHITBY, M.B., B.Ch. Camb.,
ASSISTANT PATHOLOGIST, MIDDLESEX HOSPITAL,
AND
R. JACKSON, M.B., B.Ch. Camb.,
LATE HOUSE PHYSICIAN TO THE HOSPITAL.

In this case the clinical findings and blood pictures were similar to those found in the aplastic type of pernicious anæmia occurring among munition workers during the late war. It is a significant fact that the patient was by trade a "film varnisher"—an occupation involving the continuous use of some form of "dope"—but we have been unable to trace any previous cases of disease among such workers or to find any evidence for the occupation being the primary cause of the disease.

The patient, A. C., aged 51, was admitted to the Middlesex Hospital under Dr. C. E. Lakin in March, 1924. He complained of soreness of tongue and mouth, and chronic diarrhœa with abdominal pain, all of about three months duration. He had been compelled to cease work a month before admission on account of lassitude, dizziness, and pains in the lower limbs. He had never been abroad.

*Condition on Examination*—The patient was emaciated and anæmic; teeth very decayed, and tongue, mouth, and fauces painful and ulcerated. The tongue showed numerous eroded patches and superficial cracks, whilst margins of gums were ulcerated and exuded a foul discharge. The whole condition of the mouth was suggestive of sprue, but no other sign of this disease was found. The circulatory, respiratory, and urinary systems were normal.

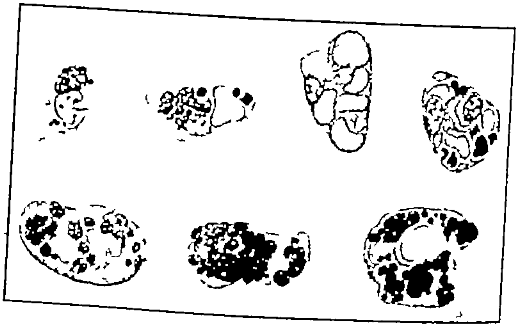
*Condition on Admission*—The temperature was subnormal, but afterwards remained slightly raised. The diarrhœa was relieved by rectal wash outs with a solution of borax. The mouth condition was treated by irrigation and mouth washes, the teeth being cleaned up with a solution of citric acid. Iron and arsenic were given intramuscularly and by the mouth. Four weeks after admission severe vomiting after food began. The patient became thinner and paler and died painlessly of asthenia ten weeks after admission, having been comatose during the last fortnight. Bacteriological examinations of the stools showed nothing abnormal. Examinations of the blood were made at weekly intervals. No nucleated forms of red corpuscles were ever found, but the films were notable for the large numbers of megalocytes present. The colour-index was usually over 1. The results are recorded in the table

*Blood Examinations.*

| Date in 1924 | Erythrocytes (in millions) | Hæmoglobin | Colour-index. | Leucocytes | Polymorphonuclears % | Lymphocytes % | Large mononuclears % | Eosinophiles % |
|---|---|---|---|---|---|---|---|---|
| 2/4 | 1,920 | 36 | 0·9 | 2,800 | 58 | 36 | 5 | 1 |
| 9/4 | 1,200 | 38 | 1·6 | 2,700 | 46 | 48 | 6 | 0 |
| 17/4 | 1,780 | 36 | 1·0 | 3,400 | 58 | 36·5 | 5·5 | 0 |
| 20/4 | 1,800 | 32 | 0·9 | 4,900 | 60 | 32 | 8 | 0 |
| 6/5 | 1,770 | 30 | 0·9 | 4,500 | 61·5 | 36·0 | 2·5 | 0 |
| 16/5 | 1,480 | 30 | 1·07 | 3,100 | 57·5 | 37·25 | 5·25 | 0 |
| 21/5 | 1,500 | 28 | 0·9 | — | — | — | — | — |
| 24/5 | 1,040 | 32 | 1·1 | 3,000 | 49·0 | 46·0 | 5·0 | 0 |

*Remarks*—April 2nd, 9th, 17th, 20th, May 6th, 16th Large numbers of megalocytes Platelets 20,000 per c.mm Few poikilocytes May 21st Megalocytes very numerous May 24th Platelets nil seen.

*Post mortem Examination*—The main post-mortem findings were syphilitic aortitis and a small dark fibrous spleen The liver gave a faint reaction for iron with potassium ferrocyanide and hydrochloric acid, the blue colour appearing after about three minutes. The diploë of skull and marrow of ribs and sternum were light yellow in colour The marrow of right femur was yellow and fatty throughout its en length except for an area occupying upper third of sh and extending slightly into the neck of the bone, which somewhat soft and creamy red in colour. Wasserma reaction, performed post mortem, positive. Several bl films and a section of blood clot were examined from po mortem material, but no nucleated forms of red cells w found. A section of liver showed that the cells contained quantity of iron pigment in the state of fine granules, b there was no destruction of liver tissue A section of t area of reddish marrow in the femur showed both leuc blastic and erythroblastic cells Myeloblasts and vario forms of myelocyte were present. All stages of developme of red blood-cell could be seen: megaloblasts with blui purple protoplasm, others more hæmoglobinised but st retaining the megaloblast nucleus, normoblasts, some large size, normal-sized red cells and megalocytes in fa numbers. In addition to above, and forming the mos striking feature of sections, were very numerous phagocyt cells. These were variable in size and shape, some spherical others oval or irregular, and most of them of large size. The pale staining reticular nucleus of these cells lay usually towards the periphery of the cell and was oval or kidney shaped; the protoplasm, faintly staining and often hardly visible, was, in the majority of cases, stuffed with red cells and pigment. Every form of red cell—megaloblasts, normoblasts, and mature cells—could be found within these phagocytes; they also occasionally contained leucocytes. The pigment, which was found exclusively within the phagocytes, was in the form of brownish granules ranging in size from fine particles up to half the size of a red cell. Sections stained for free iron, when viewed with the low power, showed blue spots scattered thickly over the field, with the one-twelfth objective these spots were seen to be phagocytes laden with blue iron containing granules of varying sizes corresponding to the brownish pigment granules. (See figure.) Coliform bacilli in clumps were evident in one or two places in the bone-marrow section.



Drawing of a series of phagocytes found in sections of the bone-marrow The upper four cells stained by Leishman's stain, the lower three stained to show the coarse granules of iron pigment

### *Phagocytosis of Red Cells.*

Phagocytosis of red cells by cells of the liver, spleen, lymph glands, and bone-marrow has frequently been described, and Aschoff [1] has drawn attention to the fact that it may sometimes become the predominant factor in blood destruction. Peabody and Broun [2] have found that a certain amount of phagocytosis of erythrocytes occurs in normal bone-marrow, and to a greater extent in a variety of pathological conditions, particularly cirrhosis of the liver, and infectious diseases such as typhoid, tuberculosis, and pneumonia, but in no disease have they found the phenomenon so marked as in the acute stage of pernicious anæmia, of which they examined ten cases. Their description of the latter is remarkable in that the phagocytes contained large numbers of red cells, but less pigment than the control cases. Turnbull's [3] findings in sections of the bone-marrow from a case of aplastic anæmia due to tri-nitro-toluene poisoning are very similar to our case.

The question naturally arises as to whether the anæmia is due to the phagocytosis or whether the phagocytosis is merely a removal of damaged cells and of pigment, both of which are the product of some other agent. The histological evidence indicates that the bone-marrow phagocyte ingests the red corpuscle, and that the pigment is formed from the hæmoglobin within the phagocyte. This is suggested, in our case, by the presence in the phagocytes of red cells—especially megaloblasts—which are apparently intact, and by the fact that the pigment was confined to the phagocytes. It is improbable that there would be such a complete phagocytosis of all pigment if this was originally formed outside the ingesting cells

*Significance of Megalocytes in Aplastic Anæmia.*

The blood counts of this case showed a severe anæmia with the high colour-index characteristic of the pernicious type, whilst the entire absence of nucleated forms of red cells indicated that the anæmia was what is commonly described as 'aplastic" Megalocytes were a notable feature in all blood films These cells, so characteristic of pernicious anæmia, are usually regarded as the special product of the bone-marrow when stimulated by a toxin, undoubtedly they serve a useful function in severe anæmia, for they are usually fully hæmoglobinised and capable of carrying a large quota of oxygen. Their origin is obscure, though it is conceivable that they are a close relation of the megaloblasts, if the normal evolution of the erythrocyte as demonstrated by Turnbull[4] be accepted Normally, the megaloblast is a cell with a reticular nucleus but with no hæmoglobin in its cytoplasm, and it becomes a normoblast by the condensation of its nucleus and cytoplasm. The young normoblast still possesses no hæmoglobin, but the acquisition of the latter substance by the normoblast coincides with the extrusion or disintegration of its nucleus and its conversion into a normal erythrocyte. Aschoff[5] states that megaloblasts are not found in normal marrow, but the evolutionary process, as described by him, is essentially the same as the above if one omits the first stage.

In severe anæmia the megaloblast is seen in the bone-marrow (and often in the peripheral circulation) as a hæmoglobinised cell, and there appears, therefore, to be a stimulus to an early and complete hæmoglobinisation of an immature red cell—a cell which normally contains no hæmoglobin. In parallel with the normal process, there should be a tendency for the cell to shed its nucleus coincident with its acquiring hæmoglobin. It seems reasonable to suggest, therefore, that megalocytes (which are frequently associated with hæmoglobinised megaloblasts) are non nucleated forms of megaloblasts and that they provide a short cut from the megaloblast to a hæmoglobinised non nucleated red cell in times of need.

*Condition of Bone-marrow in Severe Anæmia.*

The bone-marrow in cases of severe anæmia appears to react not only by producing large numbers of corpuscles to compensate for the destroyed cells, but also by hastening the hæmoglobinisation process, in an effort to provide cells of any kind so long as they are capable of carrying oxygen. In the ordinary plastic type of pernicious anæmia with the typical hyperplastic bone-marrow both these compensatory processes appear to be in action. In the classical case of aplastic anæmia described by Vaquez and Aubertin[6] both these processes were in abeyance, for no abnormal cells were found in the peripheral blood and there was no hyperplasia of the bone-marrow In the series of cases of aplastic anæmia recorded among munition workers during the late war,[7] in the series of cases collected by Dyke,[8] and in our case anisocytosis has always been noted, but with little or no hyperplasia of the bone-marrow In such cases, characterised clinically by an entire absence of remissions, the main compensatory mechanism appears to be the early hæmoglobinisation of such cells as are produced by the marrow Our case showed a slightly hyperplastic area of bone-marrow in the femur, which on section showed that the main erythroblastic activity was megaloblastic and megalocytic—a fact which supports the view expressed above on the origin, function and significance of the megalocyte. In Dyke's series of cases stress is laid on the demonstration of a bacterial infection of the bone-marrow; this was present in our case also we regard it as merely a terminal event in the course of the disease

Our thanks are due to Dr C E. Lakin for permission to publish this case and to Dr S L. Baker for his report (embodied in the text) on the bone-marrow section.

## THE BIOCHEMICAL ACTION OF INTRAVENOUS ANTIMONY TARTRATE INJECTIONS.

BY J B CHRISTOPHERSON, C.B.E, M.D. CAMB, F R C P. LOND, F R C.S. ENG.,
PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS,
AND
S ROODHOUSE GLOYNE, M.D. LEEDS, D P H.,
PATHOLOGIST TO THE HOSPITAL.

Antimony tartrate, either the potassium or sodium salt, is a simple inorganic compound of antimony with the tartrate acid radicle $(K(SbO)C_4H_4O_6)_2$, $H_2O$ It is readily soluble in water and other fluids, and when dissolved is not easily disintegrated. When injected into the blood stream in a concentration of 1 gr in 2 c.cm. of water* it has no action on the cellular constituents of the blood nor upon the endothelial lining of the vessels, and remains, apparently, in simple solution in the serum. It seems, however, to have a selective action on certain organs, tissues, and cells, and within a few minutes of reaching the general circulation it has commenced to exert its physiological effects

### (A) *Physiological Effects.*

Discomfort or pain in the chest and a dry cough mark its presence in the mucous membranes of the bronchioles, a feeling of constriction in the throat its effect on the laryngeal mucous membrane, nausea, sickness, colic—and later diarrhœa—its presence in the mucous membrane of the bowel, a desire to micturate its effect on the urinary system, and dizziness or headache its effect on the cerebrum. These are all striking results indicating rapid and early physiological action, and yet when contrasted with the immediate physiological effects of oral, hypodermic, or intramuscular administration of the drug they are insignificant. There is, however, one alarming biochemical action which may follow intravenous administration—viz., shock. This effect is apparently not due to an overdose in the ordinary accepted use of the term, but rather to individual susceptibility or possibly true *anaphylaxis* In such a case it may happen that an adult injected three times a week will, after a dose of 1½ gr, become clammy with perspiration and pale, will exhibit dilated pupils, sighing shallow respirations, general weakness, and painful extremities If the dose be repeated after two days these signs and symptoms recur; in fact, once having upset the patient's antimony tartrate equilibrium in this way he appears to remain hypersensitive.

A later physiological effect of intravenous antimony injections is shown by rheumatic pains in joints—sufficient to prevent sleep—and even paresis of muscles These rheumatic pains occur when the course is in full swing, come on some hours after an injection, and last for six or eight hours. They are repeated after the next injection if the dose is not reduced. Still later physiological effects of intravenous injections of antimony tartrate are certain skin phenomena, most conspicuous in Africans with brown (Arabs) or black (Negro) skins. The first of these manifestations is an immediate temporary flush around the site of the injection—well seen in the white skin of Europeans—and an exaggeration of any rash which may be present—e.g., psoriasis. Later a condition of "goose-skin" may occur. In the case of a negro to whom 60 gr. had been given over a period of three months a leucoderma followed, producing a de-pigmentation resembling "piebald" skin. Still later, with larger doses, the patient may experience fullness and pain in the hepatic region, and even jaundice may supervene.

---

* One grain or 0·065 gramme of antimony tartrate in two cubic centimetres of water Throughout this paper the amount of the salt is given in grains and the amount of solvent in cubic centimetres.

Death has occasionally been known to result from intravenous injection of antimony. An unpublished case is known to the writers in which a single dose of 13 gr. given inadvertently, owing to a mistake in dispensing, proved fatal in 12 hours to a case of bilharzia. This case is referred to below.

The toxic effect of antimony salts on animals may be seen from Table I., in which the salts are arranged in order of toxicity. This table has been compiled from the work of Fargher and Gray.[1]

In Table II. it should be noted that the most toxic contains the smallest percentage of antimony and is the least soluble.

The symptoms and signs which follow prolonged intravenous injections of antimony tartrate appear to be typically allergic. The patient becomes hypersensitive and intolerant of small non-toxic doses which would have no ill effects on an individual previously uninoculated. The phenomenon of drug allergy is now well recognised and has been described in connexion with glucosides, alkaloids, essential oils, certain metals, halogens, and coal-tar derivatives (Kolmer[2]). In the majority of cases the most marked effect appears to be produced on the liver and kidneys.

Apart from these signs and symptoms of hypersensitivity after the intravenous injection of antimony tartrate, two therapeutic effects are known: (1) parasito-tropic and (2) organo-tropic (Ehrlich). The former is well recognised in the treatment of tropical disease. The latter, however, is not so generally recognised, and it was with a view to elucidating some of the problems connected with this organo-tropic effect that the following clinical and experimental investigations were made.

TABLE I.

| Name. | Formula. | Per cent. antimony. | M.L.D. per K. | Weight of antimony in M.L.D. | 100 parts water dissolve at 18° C. |

A.T. = Antimonyl tartrate.

## (B) *Clinical Tests.*

Psoriasis was chosen for these tests because of its chronic intractable, generally incurable, nature. The first case treated was that of a war pensioner with moderately severe psoriasis. After a number of injections the skin condition cleared and five years later there had been no return of the condition. The next case was that of a girl, aged 11, with intractable psoriasis of scalp, face, trunk, and limbs (she could not walk). She was given 23 gr. over a period of ten weeks and the psoriasis practically disappeared. Four other cases were also treated, all of them of long standing, with head, face, hands, legs, and feet affected; one had been in this condition for 14 years, a second for 14 years, and the other two for 8 and 4 years. All of them were incapacitated by their ailment. Although each case showed improvement after a few injections, it was not until after some months—in some cases with intervals of rest—that the psoriasis disappeared.

There is nothing sensational about these cases. The antimony acted probably not directly on the psoriasis—it does not act when applied locally—but indirectly through its general physiological effect on body tissues through which it produced a marked improvement on the clinical condition of the patients. Antimony has a marked effect on the liver, and it seems possible that some alteration of protein metabolism may be produced. A small dose may cause increased cellular activity, a larger dose cellular degeneration, and an actual toxic dose cellular destruction.

## (C) *Histological and Experimental Tests.*

The toxic effects of antimony salts on animal tissues have been chiefly investigated by oral administration. In such cases, as is well known, the effect is that of a gastro-intestinal irritant, and most of the published work lays stress on this particular aspect of the question. Remote effects on the liver, kidneys, and heart have been noted, and Wynter Blyth[3] quotes experiments by Levin on rabbits fed by mouth with antimony, in which these effects on the viscera were observed. Korns[4] has also recorded a series of experiments on rabbits, injected intravenously, in which fatty degeneration of the liver is mentioned as occurring in several cases.

An opportunity was given us of examining sections of the viscera from a man suffering from bilharzia who was given intravenously 13 gr. of antimony tartrate by mistake. The liver showed signs of marked degeneration, the protoplasm of the hepatic cells was granular, vacuolation was marked, whilst the nuclei of the cells stained badly or not at all. The blood capillaries were distended and here and there were small patches of blood pigment. The interstitial tissue of the organ was also largely destroyed except immediately round the vessels. In the kidney there was, in certain portions of the organ, almost complete destruction of the epithelium of the tubules, especially of the convoluted tubules, with an invasion of leucocytes around, whilst the glomeruli were also degenerated and structureless. In other areas the destruction of the tubules had not progressed so far, a certain amount of detail could still be made out, and the glomeruli were intact. In these areas the vessels were dilated and leucocytic migration had occurred.

The following experiments were made with the object of investigating these questions further in animals.

Four rabbits were inoculated intravenously with varying doses of antimony tartrate in distilled water. The first animal was given ¼ gr. in 0·25 c.cm. water. The rabbit died during the night and was found to have hæmorrhage into the lungs and spleen, pericardial effusion, and the bladder distended with urine. Sections of the lungs showed dilatation of blood capillaries with minute extravasations of red blood corpuscles. The kidneys exhibited cloudy swelling of the cells of the convoluted tubules and dilatation of capillaries. In some tubules there was definite vacuolation of the cells. The straight tubules appeared to have escaped damage. The spleen showed two or three areas of hæmorrhage beneath the capsule, but no other changes were noted. The liver showed granular protoplasm in the hepatic cells.

The second rabbit received ⅛, ¼, and ½ gr. of antimony tartrate in 0·25, 0·5, and 1 c.cm. water respectively, at intervals of 18 hours. The animal died the day after the last injection. At the autopsy there was a small pericardial effusion, the bladder was distended with urine, the lungs congested and showing a few patches of hæmorrhage. Histologically the most marked change was in the liver, in which the hepatic cells of the lobules showed degeneration and vacuolation.

The third rabbit received ¼ gr. in 1 c.cm. water and died two days later. Here again the autopsy revealed pericardial effusion with dilated vessels in the pericardium, hæmorrhage in the lungs and spleen, peritoneal effusion, and a distended bladder. The liver was pale, and sections showed degeneration and vacuolation of hepatic cells as in the previous case.

The fourth rabbit, weighing 2 kilos, survived nine injections given during the course of 16 days, the doses rising from ⅛ to ¾ gr. and totalling 4¼ gr. The rabbit became ill the day after the last injection and died 24 hours later. At the autopsy the pericardium and peritoneum contained small effusions and the liver was pale, but no other lesions were noted. On section the liver showed very marked degeneration and vacuolation of the hepatic cells with destruction of nuclei; the central portions of the lobules were most affected.

An attempt was next made to protect a rabbit of approximately the same weight against the toxic effect of intravenous injections of antimony tartrate by injecting—again intravenously—5–15 minutes after each dose of antimony a solution of sodium thiosulphate. The animal was given eight injections of antimony, rising from ⅛ to 1 gr. and totalling 4¼ gr., during a period of 23 days. Each injection was followed by sodium thiosulphate, 0·6 gr. in the first three injections and 1·2 gr. in the others.

A control rabbit inoculated intravenously on eight occasions with doses of sodium thiosulphate alone, rising from 0·6 to 4·5 gr., showed no signs of discomfort.

### *Discussion and Conclusions.*

1. Patients subjected to a prolonged course of intravenous injections of antimony frequently exhibit signs of hypersensitivity—presumably an example of drug allergy—with non-toxic doses. 2. It is suggested that the signs of this hypersensitivity may be due to an alteration of protein metabolism and in extreme cases may resemble true protein shock. 3. The viscera of a man who had died from accidental error of dose of intravenous antimony showed degeneration and destruction of parenchyma of liver and kidneys. 4. In a series of four rabbits which succumbed to intravenous injections of antimony tartrate, two of the series died after initial doses of ¼ gr., a third after three doses of ⅛, ¼, and ½ gr., and a fourth after nine doses rising from ⅛ to ¾ gr. and totalling 4¼ gr. 5. The post-mortem changes noted in these animals were: (*a*) dilatation of blood capillaries, (*b*) effusions into serous membranes (pericardium and peritoneum), (*c*) hæmorrhages into lungs and spleen, and (*d*) retention of urine. 6. The chief histological lesion noted in these animals was degeneration of the hepatic cells. Similar, but less constant and less marked, degenerative changes were found in the kidney tubules. 7. An attempt was made to protect a rabbit against the toxic effects of antimony by injecting sodium thiosulphate shortly after each dose of the antimony. The animal died after receiving 4¼ gr. of antimony over a period of 23 days. This compares favourably with the fourth rabbit of the preceding series, which died after 4¼ gr. in 16 days without attempted protection with sodium thiosulphate.

## A CASE OF AMŒBIC DYSENTERY CONTRACTED IN ENGLAND.

BY MARTHA N. RUSSELL, M.R.C.S. ENG.,
HOUSE PHYSICIAN, ROYAL FREE HOSPITAL.

THE following case of amœbic dysentery is of particular interest in that the disease was contracted in England.

B. H., aged 38, was admitted to the Royal Free Hospital on Oct. 10th, 1925, complaining of diarrhœa, with bright red blood and mucus in the motions. She had suffered from this complaint for three years, and gave a history of sudden onset while she was engaged in cooking for a large institution in Manchester. When first admitted to the hospital she was having about six stools in 24 hours; these consisted chiefly of mucus and blood, there being very little fæcal matter present. On pathological examination enormous numbers of the cystic and vegetative forms of *Entamœba hystolytica* were found. After three courses of emetine—emetine hydrochloride gr. ½ hypodermically night and morning for three days—at three weekly intervals, the condition completely cleared up.

The pathological evidence and the cure by emetine leave little doubt that this was a case of amœbic dysentery. The interesting points in this case are the facts that the patient herself has never been out of England and that, so far as she knows, none of her associates have suffered from the same complaint.

I am indebted to Dr. W. P. S. Branson for liberty to publish this case.

## THE STORY OF A SYRINGOMYELIA.

BY W. S. HEDLEY, M.D. EDIN., M.R.C.S. ENG.
LATE PHYSICIAN IN CHARGE OF ELECTRO-THERAPEUTIC DEPARTMENT, LONDON HOSPITAL.

FOR the last 30 years I have had continuously under observation a case which, on account of its late appearance, its destructive onset, its slow progress, and its already long duration, seems deserving of record.

I first saw the patient, aged 35 years, in 1896. She had been of active habits up to five or six years ago, when she began to feel ill-defined sensations of "tingling" in both arms and shoulders. This disappeared, but shortly afterwards weakness and wasting of the arms became very evident, and advanced rapidly.

On examination the entire musculature of the shoulder-joint was atrophied and showed diminished or lost response to electricity, and in places R.D. The deltoid was powerless, and the triceps could not raise the arm against gravity.

Slight voluntary movement at the elbow was possible (by supinator longus rather than by biceps). Wrist movements weak. Flexion and extension of the fingers remained, but there was paralysis of interossei. A mass of brawny inelastic tissue lay beneath the skin of the scapular region. Tactile sensibility was not much impaired, but there was dullness to painful impressions and, most significant, loss of discrimination between "hot" and "cold," and in places actual reversal of these impressions.

It was fairly evident that the case was one of syringomyelia and that the cervical plexus had, as usual, borne the brunt of its onset. Some weakness in the legs was complained of, but she said that she could (and did) walk three or four miles a day without serious fatigue.
